DISEASES OF THE SALIVARY GLANDS

A. CHERCHTENBERG, M.D.
Ann Arbor, Mich.

The secretions of the oral cavity are derived from a number of secretory glands, the parotid, submaxillary and sublingual glands; the glands of Blandin and Nuhn, the palatal glands, Moore glands and a number of small mucus-secreting units situated in the floor of the mouth and the buccal surfaces of the cheeks.

For practical purposes I may limit my consideration to the parotid and submaxillary glands. These are the two chief structures which enter into my discussion because they are the ones most frequently affected by pathologic conditions which come to the attention of the otolaryngologist. The sublingual glands are of lesser significance. Aside from the fact that they may enter into a somewhat vicarious form of ranula, they hold little interest for the otolaryngologist. Occasionally a cyst of one of the sublingual glands will become obstructed, causing a myxomatous degeneration and a swelling in the floor of the mouth which has been called ranula. This, however, is not a true ranula. The ranula is of teratologic origin and represents heterotopias or ectopias of pharyngeal mucosa as observed in the branchial cysts. A microscopic section through the wall of a congenital ranula arising from the second branchial arch reveals a characteristic admixture of stratified and columnar epithelium in contrast to mucous membrane observed in those cysts produced by a myxomatous degeneration of a gland in the floor of the mouth.

SIALOLITHIASIS

A common cause of acute infection in the salivary glands is the presence of a salivary calculus. The influences responsible for a salivary stone are not fully recognized, although in some instances the calculus can probably be ascribed to inflammatory reactions within the gland. The infected gland thus furnishes a changed secretion which favors the precipitation of elements responsible for the calculus. Perhaps in some cases foreign bodies serve as a nucleus for formation of the stone. It has been reported in the literature that ductogenic actinomycosis may be the factor responsible for a salivary calculus. This theory, however, does not seem to be plausible in view of the fact that salivary stones frequently occur in horses, but these animals are never affected by actinomycotic infections. More-

over, one never observes salivary stones in cattle, which are so often affected by this disease.

Salivary calculi usually originate within the gland structure in the form of small concretions which are carried along with the salivary current to become lodged in the gland duct. Here they become enlarged by deposits of bacteria and phosphates. Any of the salivary glands or ducts may be the site of calculus formations, but the most frequent location is Wharton's duct, after which, in order of frequency, one finds the stones in the submaxillary glands, the parotid glands and Stensen's ducts.

Signs and Symptoms.—The degree of symptoms depends on the size and location of the stone. If it lies within the gland structure, the patient may experience only a mild intermittent feeling of irritation and discomfort in the affected region together with moderate swelling. If, however, the stone is in the duct the symptoms may be severe, characterized by a sudden sharp pain when the salivary flow is stimulated and rapid, and painful distention of the gland. In the course of twelve to forty-eight hours an inflammatory reaction may occur, due to the retention of infected secretions. Pus may be found in the floor of the mouth, together with swelling of the tissues along the course of the duct with deviation of the protruded tongue when the submaxillary gland is involved. General reactive symptoms, malaise and fever are occasionally in evidence. The floor of the mouth may be dry, and frequently no saliva will be found flowing from the obstructed duct when the patient is asked to suck a piece of lemon. Palpation of the duct may express pus or reveal the location of the stone.

When the calculus is in a salivary gland, a probe passed into the duct fails to locate the stone. In these cases the most useful data are supplied by a roentgenographic examination of the gland. If the calculus is large enough to cause obstruction and particularly when it contains calcium salts as its chief constituent, it is usually demonstrable in a roentgenogram.

Treatment.—Treatment varies with the stage of the condition. When a gland is acutely inflamed, palliative therapy until the acute inflammation has subsided is, I believe, the procedure of choice. This is accomplished by the administration of sulfadiazine and penicillin, hot irrigations of the mouth and external dressings, hydration, suberythema doses of roentgen rays and gentle probing of the duct. The latter may produce sufficient dilatation of the duct to cause a spontaneous expulsion of the stone.

During the interval between acute inflammatory reactions the stone should be removed surgically. A 2 per

cent solution of procaine hydrochloride is injected about the papilla of the duct and along its course posteriorly to the region of the calculus. The papilla is then grasped and cut off. This procedure greatly facilitates the introduction of a probe into the duct. The duct is then split open along the probe with a knife or canaliculus scissors until the stone is reached and removed with a forceps or curet.

The intraoral approach is obviously the one of choice. It is a simple procedure, devoid of complications, and can be safely executed without the danger of producing a salivary fistula. The operative wound in the floor of the mouth need not be closed by sutures. The wound heals kindly and the duct rehabilitates itself with normal patency and perfect function, even though its papilla is removed and its walls are extensively damaged in the manner described.

Occasionally the presence of a stone or multiple stones within the submaxillary gland, associated with a chronic inflammation, gives rise to the necessity of removing the entire submaxillary gland. This can easily be accomplished by an external approach, although one must have proper respect for the hypoglossal nerve, which may come within the field of operation if the excision is carried for any appreciable distance mesially and posterior to the gland. In the vast majority of cases, however, the stone can be removed by the intraoral route, a procedure which is to be advocated when feasible. Medicamentous stimulation of salivation in order to promote the expulsion of fragments of stone is usually not successful. It frequently causes pent-up secretions within the glands, with pain and the risk of a secondary infection.

THE PAROTID GLAND

Inflammations of the parotid gland may arise from three sources: (1) parotid infections resulting from foreign bodies in the duct, particularly the salivary calculus; (2) abscesses occurring as a complication of abdominal operations, and (3) inflammatory disease arising as a result of direct extension from neighboring infections.

When stone in Stensen's duct is responsible for infection in the parotid gland it can be removed by the intraoral route as described for stone in the duct of the submaxillary gland. Stensen's duct is probed and split open until the calculus can be grasped and recovered. The duct mends and restores its patency in a phenomenal manner and the risk of producing a salivary fistula is of no concern. I have never found it necessary to excise the entire parotid gland for multiple calculi and their associated inflammatory reactions, although the literature refers to several cases of recurring phlegmonous processes which called for the total extirpation of the parotid gland at the cost of destroying the facial nerve. In a few instances, however, I have made several incisions into the parotid gland for the removal of multiple calculi, and fortunately the patients thus treated went on to satisfactory recoveries. It is only necessary to reflect the skin and subcutaneous tissue from the parotid gland, identify the stones by palpation, incise the gland to expose them and thus effect their removal. The facial nerves are deeply situated in the tissues of the parotid gland so that it is possible to do considerable damage to the superficial structures without danger of injuring the fibers of the nerve. Every

effort should be made to tease out the various divisions of the facial nerve and protect them when possible. It is interesting to note how extensively the parotid gland may be excised with preservation of the important branches of the facial nerve. In a number of instances I have removed the entire parotid gland which was the seat of infiltrating tumors without serious injury to the main divisions of the seventh nerve.

Sir William Osler¹ in 1902 called attention to the occurrence of inflammation of the parotid gland "in connection with injury or disease of the abdomen or pelvis." No explanation was offered, but in the light of recent studies on water balance, it is highly probable that the etiologic influence was dehydration. I have never seen a parotid abscess develop in a patient whose fluid requirements were adequately fulfilled. The parotid gland, devoid of a protective flow of secretions, may become infected by a retrograde extension of mouth organisms through the duct, particularly in the presence of septic oral cavities.

One must also call attention to another possible etiologic factor in this group of patients: namely, the injury that may be done to the parotid gland by the anesthetist who forcibly holds the jaw forward during anesthesia. Firm pressure back of the ramus of the mandible for an hour or more may injure the parotid gland and devitalize it to the extent that it becomes a fertile soil for the growth of infection.

I need not describe the anatomic relationships of the parotid gland and particularly its intimate association with the pharyngomaxillary fossa. Through this space the inner prolongation of the parotid gland (carotid lobe) is open to infection on all sides. By this route infections of the cervical vertebrae and inflammatory processes which originate in the peritonsillar and retropharyngeal regions may invade the parotid gland. By the same token, infections originating in the parotid gland, possibly secondary to a furunculosis of the external auditory canal, may extend medially through the carotid lobe to the pharyngomaxillary fossa and thence to the region of the pharynx.

Treatment.—The use of the sulfonamide compounds and the antibiotics has greatly altered the course and prognosis of inflammation of the parotid gland. Seldom does this lesion eventuate in the formation of an abscess which requires surgical intervention. When incision is indicated, however, massive drainage of the gland is advocated. This can be obtained by an incision which begins above at the level of the zygoma and extends downward in front of the external auditory canal, parallel with the ramus of the jaw and forward beneath the angle for a distance of 2 or 3 cm. along the inferior margin of the mandible. The skin and subcutaneous tissues are reflected forward, thus exposing the entire lateral surface of the gland and facilitating massive drainage of this structure.

Another important factor in the treatment of parotid abscess is hydration. The average adult person requires approximately 3,500 cc. of fluid in twenty-four hours and it is important that the patient be given this quantity in order to promote normal functions of the excretory organs of the body. If the patient is not receiving an adequate supply of fluid each day by mouth, it should be administered by the intravenous route.

1. Osler, W.: *Principles and Practice of Medicine*, New York, D. Appleton and Company, 1892.

5 per cent solution of dextrose serves the purpose well. Other palliative measures of doubtful value are hot external dressings, suberythema doses of roentgen rays, gentle probing of the duct and diathermy for the relief of pain.

Certain chronic conditions occasionally involve the salivary glands. Syphilis is a rare occurrence. A few cases have been reported in which the glands were the seat of tertiary manifestations of the disease. The diagnosis was based on a serologic examination, evidences of tertiary syphilis elsewhere in the body and therapeutic tests in some instances.

It is now considered that Boeck's sarcoid, osteitis tuberculoidea multiplex cystoides, uveoparotid fever and certain cases of Mikulicz's syndrome are representative of a noncaseating tuberculosis with variable combinations of clinical symptoms. The demonstration of tubercle bacilli, microscopic evidence of typical tubercles without caseation, the occasional transformation of these lesions into a caseating tuberculosis, serologic data and the similarity between sarcoid reactions in human beings and in certain animal species are obviously arguments in favor of a tuberculous causation.

Actinomycosis of the salivary glands may occur as a secondary infection from the mouth. It is characterized by a chronic inflammatory swelling at the angle of the jaw or in the cervical region with the formation of numerous sinuses which discharge pus. Examination of the pus reveals the typical sulfur granules which when compressed between cover glasses and examined microscopically show the ray fungus of actinomycosis. While radical excision or cauterization of the inflammatory mass, roentgen therapy and the administration of potassium iodide have been the sovereign remedies, many of the lesions promptly recover by the use of sulfadiazine and penicillin. These agents have obviously greatly altered the therapy and prognosis of this lesion.

I cannot pass by without simple mention of the occasional patient who reveals an organic lesion responsible for a dysfunction of the salivary glands. The patient complains of a dry mouth. The mucous membrane is parched, a wooden tongue blade drawn over the mucous membrane meets the resistance of a sticky surface, the tongue may appear desiccated with thin crusts on its dorsum and pressure on the glands reveals little or no saliva. Even when the patient is asked to suck a piece of lemon salivation does not occur.

The pathologic change responsible for dysfunction cannot be revealed. Nevertheless, it represents some physiologic disturbance in the end organs of the nerves supplying the salivary glands. Occupational hazards such as exposure to organic dusts and zinc poisoning have been responsible in a few of my patients. Botulinus poisoning was the cause in 1 person.

Pilocarpine therapy is frequently most effective in these cases. Pilocarpine hydrochloride or pilocarpine nitrate is taken orally in 8 mg. doses three times a day. It should be administered before meals in order to promote salivation when it is most needed. The drug seems most effective when the patient is in a mild state of acidosis. Thus it is recommended that the alkalis be restricted in the diet and that the patient be given 3 Gm. of ammonium chloride with meals three days "on" and two days "off" during the uninterrupted administration of the pilocarpine.

TUMORS

The vast majority of neoplasms originating within the salivary glands fall into the classification of the mixed tumors. These lesions obviously are of teratologic origin, caused by some disturbance or irregularity in the mechanics of embryonic development. They frequently put in their appearance during the third or fourth decade of life, grow slowly or not at all for many years and finally burst forth with a flourishing growth which calls for their removal. Their clinical behavior suggests an origin from an embryonal rest, aberrant structures or a superfluous collection of cells.

It is to be emphasized that these lesions are vicious and devastating in their behavior. They appear usually in young adults as a more or less benign lesion which grows insidiously but resolutely in the direction of a malignant neoplasm. I have frequently observed that years after what appeared to be a successful operation for the removal of a mixed salivary tumor the lesion has returned with alterations which were clearly those of a rapidly proliferating malignant neoplasm.

The treatment is surgical. One cannot emphasize too strongly that the fate of the patient lies in the hands of the first surgeon. If he is successful in removing every vestige of the neoplasm, and this can usually be done even though all of the parotid gland must be removed, there is little danger of a troublesome recurrence. The first surgeon must not fail to eradicate the lesion so completely that no portion of it remains in the field of operation.

CONCLUSIONS

The etiologic factors responsible for inflammations of the salivary glands are foreign bodies—particularly the calculus—injury or disease of the abdomen or pelvis and extension of infection from neighboring tissues. Injury and dehydration are also potent influences in the origin and development of infections in these structures.

Effective agents in the therapeutic armamentarium are sulfadiazine and penicillin. Hydration must be instituted and maintained. Wide incision and massive drainage are required when a circumscribed collection of pus is present.

Chronic infective granulomas are rare manifestations of disease of the salivary glands. A noncaseating form of tuberculosis is occasionally observed. The gumma perhaps is more rarely seen. Actinomycosis has responded most satisfactorily in many instances to the sulfonamide drugs and penicillin therapy.

A dysfunction of the salivary glands is occasionally the result of end organ lesions of the peripheral secretory nerves. A normal salivary flow may be produced by the administration of pilocarpine. The effect of the drug is augmented by the simultaneous ingestion of the acid-forming salt ammonium chloride.

The common neoplasm of the salivary glands is the mixed tumor. The soft tumors are more prone to exhibit carcinomatous alterations than the hard, firm ones. They are devastating in their clinical behavior in that they tend to degenerate into rapidly proliferating carcinoma. Surgical intervention which accomplishes the complete removal of the lesion is most successful. When these tumors do recur, however, they usually present frank carcinomatous alterations and further surgical efforts are futile.

ABSTRACT OF DISCUSSION

DR. LEROY A. SCHALL, Boston: Dr. Furstenberg can always be relied on to present a scholarly, scientific paper. It is refreshing to have an otolaryngologist talk about major surgery for the carotid gland. Too often we ship these cases over to the general surgeon, and it should not be. We should be able to take care of anything within our field. I feel that the salivary gland belongs to the otolaryngologist. There is little to discuss in this complete paper of Dr. Furstenberg. With stone in the duct of the submaxillary gland, we have been in the habit of putting a suture behind the stone before we start probing for it, in order to avoid pushing it back into the gland. We, too, remove the submaxillary gland when there have been repeated infections or when there are multiple stones in the submaxillary gland. What he has to say about dehydration is very important, and now when our anesthetists are so persuaded of the value of intratracheal anesthesia, perhaps we shall have fewer cases from forcibly holding the jaw forward. Intratracheal anesthesia, intravenous anesthesia and proper fluid balance, along with the sulfonamide drugs and the antibiotics, may make suppuration of the carotid gland a disappearing disease.

DR. JAMES MILTON ROBB, Detroit: I want to commend my friend, Dr. Furstenberg, on what he has been doing for a number of years, and that is bringing the attention of the otolaryngologist to the care and surgery of the salivary glands. He brings every phase of it to our attention but, as a corollary of his efforts, he also is really saying to us that the methods of general surgery, the methods of a trained surgeon, must be a part of one's efforts, and as our young men are coming along, one of the things that we must do as part of laryngology is have them trained in general surgery so that these measures that he mentions can be satisfactorily carried out.

DR. A. C. FURSTENBERG, Ann Arbor, Mich.: I wish to thank Dr. Schall and Dr. Robb for bringing out the important points that they have emphasized. I want to express my deep appreciation to you for the privilege of appearing here at this time and for the kind indulgence of the members of this section.

PERIPELVIC LYMPHATIC CYSTS OF THE KIDNEY

Report of Two Cases

A. J. SCHOLL, M.D.
Los Angeles

Peripelvic cysts of the kidney occur rarely, they are usually small in size and most cases have been noted by pathologists as incidental findings at necropsy. In only a few cases have these cysts caused clinical symptoms, and these were usually large cysts tending to distend the abdomen; their perinephric origin was in most cases recognized only on the operating table or at necropsy. Abbe¹ reported two cysts which were large enough to pass beyond the midline of the abdomen. One contained 2 pints (946 cc.), the other 12 pints (5,678 cc.) of fluid. Albarran and Imbert² reviewed 18 cases reported before 1903. Eight of these patients had been treated surgically, 4 by removal and 4 by drainage. Przewoski³ and Albarran and Imbert, as well as other authors, suggested that the cysts arose from embryonic remnants of the wolffian body. Lüdin and Howald⁴ reported a case in which a small cyst had extended into the kidney from the renal hilus. It was not connected with the pelvis or calices and contained a calcareous deposit that cast a roentgen shadow

suggesting stone. The cyst was opened and the calcareous material removed; healing occurred readily. Shih and Wu⁵ reported a case in which a cyst containing 150 cc. encroached on the lateral wall of the kidney, causing considerable distortion of the kidney. In most reported cases the cysts were unilocular, although Haslinger⁶ reported a multilocular parapelvic cyst 9 cm. in diameter that was attached to the renal pelvis. By pressure on the renal pelvis it produced stasis in the renal pelvis, causing urinary retention and infection. Haslinger thought that the cyst did not arise from the kidney substance proper but developed from a mesonephric rest or was the result of an outpouching or snaring-off of part of the renal pelvis during embryonic life. Lieberthal⁷ reported a similar case in a woman aged 50. An intravenous pyelogram showed a compression of the renal pelvis, an obliteration of the middle calyx and thinning out of the upper and lower calices. At operation a bluish translucent cyst the size of a walnut extended out from the hilus, lying between the renal pelvis and the vascular pedicle. The extrarenal part of the cyst was resected and the cavity wiped out with phenol and alcohol. The wound healed readily, and five months later an intravenous pyelogram revealed a normal renal pelvis.

Henthorne⁸ has recently called attention to the possible lymphangiomatous source of certain of these cysts. He stated that the first and most complete description of these peripelvic lymphatic cysts was given by Rivolta,⁹ who in 1889 reported the lesion found at necropsy on 2 elderly patients. Rivolta recognized that the cysts were lymphatic ectasis and quoted Virchow as authority for the occurrence of an analogous lesion in the human being; namely dilated lymphatics of the female pelvis following puerperal inflammatory disease. Henthorne found 20 such cases in a large series of necropsies. In none of his cases was the cyst of sufficient size to become clinically important. The presence of scars and cortical cysts in most of the kidneys suggests an inflammatory basis for the cysts. In 11 of Henthorne's cases in which the patients were men there was a history or evidence of obstructive, infectious or calculous disease of the kidney. Three of the 4 women had borne children and may have had renal infection during the puerperium. It is also striking that in 8 cases the patients had lesions that generally are presumed to be congenital anomalies; lymphatic ectasia occurred in other organs in 5 of these cases. Henthorne stated that from this fact it is evident, on a statistical basis alone, that the evidence for the congenital origin of peripelvic lymphatic cysts is just as good as the evidence for the inflammatory origin. The fact that the cysts occurred late in life, however, is in favor of an acquired lesion.

I have recently operated on 2 patients both of whom had large peripelvic lymphatic cysts which were of sufficient size to cause distortion of the renal pelvis and to exert pressure on the structures of the renal hilus. These cases are of interest because of the origin and large size of the cysts, their apparent relationship to hypertension and the similarity of the diagnostic signs to those of renal tumors.

REPORT OF CASES

CASE 1.—Mrs. M. R., aged 61, had a "severe" attack of renal trouble nineteen years ago, of several months' duration. For ten years she had felt tired and run down and had frequent attacks of fever, frequency of urination and dysuria; there had been no hematuria. During the last five years she had a fairly constant dull pain in the right renal area and her systolic blood pressure had been elevated; For a year it had been above 180.

Fig. 1 (case 1).—Attenuated, semicircular deformity of retrograde pyelogram (right).

Examination.—A palpable right kidney was found and the blood pressure was 178 systolic and 96 diastolic. The hemoglobin was 80 per cent and the urine contained a few white and red blood cells. The nonprotein nitrogen of the blood was 33 mg. per hundred cubic centimeters of blood. The Kline test was negative in result. Roentgenograms of the chest, gastrointestinal tract, kidneys, ureters and bladder was normal. At cystoscopy mild areal cystitis was found. Both ureters were catheterized without difficulty; the function of the left kidney was normal, that of the right moderately reduced. The pyelogram of the right kidney revealed an attenuated semicircular deformity of the renal pelvis and calices (fig. 1); the pyelogram of the left kidney was normal.

Operation.—The right kidney was exposed through a posterior lateral incision. It was somewhat enlarged and the parenchyma was thinned out, little functioning tissue remaining; a rounded tense mass could be felt in the middle portion. No definite tumor could be made out nor did the organ have the tortuous, dilated, superficial veins usually associated with renal tumors. There was no extrarenal evidence that the lesion was cystic. The pedicle was clamped, cut and tied and the kidney removed. The wound was closed in the usual manner and healed readily. Several days following operation her blood pressure had dropped to 136 systolic and 80 diastolic. One year later it was 140 systolic and 80 diastolic, and she felt exceedingly well. She had no pain, was able to do her housework and had gained 10 pounds (4.5 Kg.) since operation. She had no further symptoms of urinary infection and her urine was essentially normal.

Pathologic Data (Dr. J. H. Kahler).—The specimen consisted of a right kidney which weighed 190 Gm. and measured 9 by 6 by 6 cm. There was a cyst which protruded into the peripelvic fat. It was thin walled and bluish in color. When the kidney was opened the cyst occupied the mid portion of the kidney, and the cortex overlying the cyst was compressed and atrophic, measuring 5 mm. in thickness. There was no

communication between the cyst and the pelvis or calices. It was filled with clear, straw-colored fluid. The lining was thin, smooth and whitish. The calices were slightly dilated. The pelvic mucosa was smooth and glistening and the ureter was small and normal. The cortical markings were distinct and the parenchyma was normal except over the apex of the cyst.

Microscopic Description.—The cyst had a wall composed of collagen fibers, four to five layers thick. Its inner surface was wavy, and only an occasional nucleus was seen in the lining. It is probable that the nuclei were the remains of small endothelial cells which were markedly stretched out. They were similar in appearance to the lining cells of large, dilated lymph vessels (fig. 2). The sections through the pelvis overlying the cyst shows a normal transitional epithelial lining beneath which the stroma is edematous. A section through the middle calyx, the area in which the renal parenchyma was most thinned, demonstrated a decided condensation of the connective tissue at the calyx and compression of the adjacent collecting tubules, in many of which there were blue-staining casts.

Diagnosis.—The diagnosis was peripelvic lymphatic cyst of the kidney (718-064),¹⁰ pyelitis follicularis (719-100) and chronic pyelonephritis (722-100).

CASE 2.—Mr. L. F., aged 57 years, had pain in his left loin occasionally during the previous year; during the previous two months it had been rather severe. There had been no hematuria, frequency or nocturia, though recently he had had some bladder spasm and urgency. During the previous three years his systolic blood pressure had varied from 180 systolic and 100 diastolic to 210 systolic and 120 diastolic.

Fig. 2 (case 1).—Low power photomicrograph (approximately $\times 15$). In the center the peripelvic lymph cyst is seen as a clear space delimited by a single layer of nearly invisible endothelial cells supported by a thin fibrous wall. Loose areolar tissue containing a few vessels separates the cyst from the renal pelvis above and from renal parenchyma below.

Examination.—The patient was a heavy, vigorous man with a florid complexion. The blood pressure was 180 systolic and 100 diastolic. The hemoglobin was 100 per cent, the urine contained a few pus cells and the Kline reaction was negative. The nonprotein nitrogen content of the blood was normal.

10. The classification system used is that of Jordan, E. P.: Standard Nomenclature of disease and Standard Nomenclature of Operations, second edition, Chicago, American Medical Association, 1942.

ams of the chest, kidneys, ureters and bladder dye was seen in the left kidney in the intra-; the right renal pelvis appeared normal. scope the bladder was seen to be normal with line coming from both ureteral orifices. The phenolsulfonphthalein return was normal from the right kidney; that from the left was considerably reduced. A retrograde pyelogram of the left kidney revealed an attenuated, semicircular deformity of the renal pelvis and calices similar to that seen with renal tumor (fig. 3).

Operation.—The left kidney was exposed through a postero-lateral incision. There were many perirenal adhesions which were rather vascular and bled profusely. The kidney was slightly larger than normal, and a tense bluish thin-walled cyst was seen projecting from the renal hilus. The cyst, which was about 4 cm. in diameter, extended downward compressing the pelvis and ureter posteriorly and vascular pedicle in front (fig. 4). In an attempt to free the adhesions around the cyst it was ruptured and brisk bleeding was started which was difficult to control. The renal pedicle was then clamped, cut and tied and the kidney removed. The wound healed without trouble. Directly after operation the blood pressure was 126 systolic and 80 diastolic. During the following four months it had not gone above 136 systolic and 90 diastolic. At this time, at his last examination the patient felt well and had had no further pain or discomfort.

Fig. 3 (case 2).—Filling defect in left-sided retrograde pyelogram.

Pathologic Data (Dr. J. H. Kahler).—The specimen consisted of the left kidney, weighing 175 Gm. and measuring 12 by 7 by 5 cm. The outline of the kidney was normal; the capsule stripped with ease from a smooth pinkish red surface. There were no adenomas or scars. Protruding from the medial aspect of the peripelvic fat there was a cyst which was filled with clear fluid but which was ruptured during removal and which now contained clots from a fairly large bleeding vessel. This cyst,

4 cm. in diameter, had depressed and deformed the middle calix and by pressure slightly dilated the superior calix. The pelvis itself was not enlarged; its mucous membrane as well as that of the calices was thickened and red in color with small hemorrhagic areas. The peripelvic cyst had a smooth lining and a thin almost translucent wall. When the kidney was sectioned the markings were normal; the cortex measured 7 mm. and the medulla 9 mm.

Fig. 4 (case 2).—Peripelvic lymphatic cyst compressing renal pelvis and vascular pedicle.

Microscopic Description.—The cyst had an almost invisible layer of minute endothelial-like cells of which only the nuclei were occasionally visible. The cyst wall was formed in concentric layers of fibrocytes as in the wall of a lymph vessel. The pelvis, on the other hand, was lined by normal epithelium but its wall was decidedly thickened, particularly beneath the serosa, by pronounced edema, foci of hemorrhage and occasional small foci of lymphocytes. The epithelium and subjacent connective tissue of the calices were normal in appearance, while sections of the kidney cortex showed no vascular lesion whatever and the glomeruli appeared entirely normal. However, the tubular epithelium contained some albuminous material mixed with red cells. It is possible that this change was due to the trauma of operation, or it may have followed previous instrumentation.

Diagnosis.—The diagnosis was peripelvic lymphatic cyst of kidney (718-064) and chronic pyelitis (722-100).

COMMENT

The cysts in both cases were exceptionally large for this type of lesion and the kidney was removed in each case. The first patient was elderly and hypertensive; there was considerable destruction of the kidney and it was impossible to determine definitely whether the lesion was simply cystic or whether malignant growth was also present. Similar conditions were present in the second case except that the lower segment of the cyst was visible protruding from the renal hilus. When the cyst was opened uncontrollable bleeding was encountered from a large vessel in the deeper portion of the cyst. An attempt was made to control the bleeding by packing and suturing without success, and it

was necessary to remove the kidney. On examination of the kidney after removal a fairly large ruptured blood vessel was found in the cystic cavity. In both kidneys there was evidence of previous inflammation, a probable causative factor in the formation of lymphatic cysts.

Lymphatic cysts are lined by a single layer of endothelial cells, and in most cases where the lesion is apparent and definitely recognizable and if it is certain that no malignant growth is present, simple drainage of the cyst and partial destruction of the cyst wall would give a satisfactory result. Lieberthal,⁷ Kreutzman¹¹ and Lüdin and Howald⁴ have reported similarly located cysts, though they were not noted as being lymphatic in origin, which healed readily following such conservative measures.

The effect of removal of the cysts on the elevated blood pressure was of interest. Apparently the cysts were so located as to cause a partial constriction of the renal artery, a condition which has been shown by experiments of Goldblatt¹² and others to cause renal ischemia and hypertension. The fall in blood pressure followed immediately after operation, and, while it remained low in one case for a year, insufficient time has elapsed in either case to predict where it will eventually become stabilized. Kreutzman¹¹ reported 2 cases in which an elevated blood pressure dropped after the drainage of renal cysts; in both cases the cysts were apparently so located as to obstruct the renal circulation. In the first case a cyst protruded from the dorsum of the kidney. It was aspirated and 120 cc. of clear, light yellow fluid removed; the blood pressure dropped from 210 systolic and 108 diastolic to 140 systolic and 90 diastolic directly after operation, and three years later it was 156 systolic and 94 diastolic. In the second case a preoperative blood pressure of 210 systolic and 125 diastolic dropped to 150 systolic and 105 diastolic; three years later it had become stabilized at 170 systolic and 100 diastolic. Similar cases have also been reported by Farrell and Young¹³ and Pearce, Bower and Burns.¹⁴

Solitary cysts occurring in the body of the kidney are not uncommon. Fish¹⁵ gave three theories of their formation: (1) congenital origin, (2) vascular damage plus tubal blockage, as described by Hepler,¹⁶ and (3) embryonal rests. Beer¹⁷ in 1922 stated that the sum of the evidence offered seems to support the view that simple, serous cysts originate from the lymphatic spaces situated between the layers of the true capsule, possibly through a traumatic or inflammatory agency. While it is possible that these theories may explain the origin of the majority of solitary cysts it is rather probable that a definite number are lymphangiomatous in origin. In some cases cysts which may have started as peripelvic cysts had become so large that the point of origin could not be determined. In other cases it is not improbable that the cysts may have arisen in the lymphatics in the body of the kidney. In the cases reported the cysts were localized in the peripelvic region

at the time of operation and sufficient tissue was available for examination to make certain of their lymphatic nature.

SUMMARY

Peripelvic lymphatic cysts of the kidney, usually small and of little clinical importance, may become of sufficient size partially to destroy the kidney. These cysts are probably lymphatic ectasia associated with obstruction of the lymphatic trunks of the hilus of the kidney. Lymphatic cysts add one more to the list of types and the theories of development of renal cysts.

Two cases are reported in which lymphatic cysts extending from the hilus to the body of the kidney caused extensive renal damage and exerted pressure on the renal vessels. There was pronounced hypertension in both cases; removal of the cystic kidney caused a considerable drop in blood pressure in each case.

1930 Wilshire Boulevard (5).

ABSTRACT OF DISCUSSION

DR. BASIL A. HAYES, Oklahoma City: Two cases of peripelvic cysts have come under my observation during the past year. The first was in a woman aged 50 who had a palpable fluctuant mass in the upper right quadrant of the abdomen. Cystoscopy and pyelograms revealed the characteristic appearance of a large cyst which covered the kidney shadow and partially obscured it. On operation the cyst plainly arose from the anterior surface of the kidney about the junction of medulla and pelvis. It was so large that it had almost squeezed out the middle portion of the kidney, leaving the two poles connected by a narrow isthmus of renal tissue. The patient had had intermittent attacks of pyelitis which I considered were due to pressure on the ureteropelvic junction. The cyst was dark colored and filled with a clear fluid. On attempting to peel the wall away from renal tissue I ran into considerable hemorrhage and had to content myself with trimming the wall close to the kidney and running a hemostatic suture all the way around the cut edge. Even with this precaution the patient lost considerable blood, and I found it necessary to give her a transfusion afterward. The second case was in a man aged 55 who came to me with a stone in the left renal pelvis. On operation I found three small cysts attached to the pelvic wall. These had to be excised before I could get at the stone. I had no difficulty in doing so but here again found it necessary to do considerable tying off of blood vessels in order to stop oozing from the peripelvic fat. This tissue showed evidence of chronic inflammation and was rather vascular. Both these patients made uneventful recoveries. I regret to say that the histology was not studied in the last case, but the first one showed a dense fibrous wall, with an outer zone of compressed renal tissue. Neither had had hypertension but each had had a chronic inflammation in the renal pelvis. As to the probable origin of these structures, I am reminded by our pathologist, Dr. Bela Halpert, that the entire kidney is derived from mesodermal tissue and frequently contains rests or anlagen which could develop into cysts; also that a distinguishing characteristic of lymphatic tissue is its property to divide and redivide, forming numerous communicating spaces rather than large cavities lined by a cellular membrane. As opposed to this, epithelial rests tend to form cysts lined by a secreting membrane. Also, this tissue may transform itself into other bizarre forms, as in teratomas. This being the case, I wonder whether one could be sure that any particular cyst arose from lymphatic tissue or whether it more likely came from an epidermal rest.

DR. A. J. SCHOLL, Los Angeles: I do not believe that these cysts are as uncommon as a review of the literature suggests. I think that some cysts were so large that their point of origin was lost; also, some penetrate up through the parenchymal tissue and present themselves as simple serous cysts. The cyst walls are composed of thinned-out attenuated endothelial cells similar to those found in all lymphatic cysts. The cysts in the cases reported by Henthorne were all small, but a study of the lining cells definitely established their lymphatic origin.

TREATMENT OF MENINGITIS WITH SULFADIAZINE AND SULFAMERAZINE

WILLIAM W. ZELLER, M.D.

HAROLD L. HIRSH, M.D.

LEWIS K. SWEET, M.D.

and

HARRY F. DOWLING, M.D.

Washington, D. C.

Previous studies from this hospital have endeavored to determine the value of various sulfonamide drugs in the treatment of meningococcic meningitis and to analyze certain factors which influence the prognosis of this disease.¹ Although these studies have shown that the case-fatality rate in meningococcic meningitis could be lowered to approximately 10 per cent with the use of either sulfadiazine or sulfamerazine, it was felt that it might be possible to reduce the fatality rate still further. One way to do this, according to the opinion of some investigators,² would have been to employ larger doses of sulfonamide compounds. Motivating against such a course, however, was the expectation that renal calculi would develop in more patients if the dose of sulfadiazine or sulfamerazine were increased.

The studies of Lehr³ suggested the possibility that larger doses of sulfonamide drugs could be used without raising the frequency of renal complications by administering a combination of these drugs. He reported that the sulfonamide drugs when present simultaneously in the same solution in the free form were soluble to the extent of their separate solubilities. In other words, a saturated solution of sulfadiazine could be almost completely saturated with sulfathiazole. He demonstrated also that the acute and chronic toxicity of this drug combination for albino rats was strikingly lower than that which accompanied the administration of the same total concentration of each drug alone. Furthermore, the incidence of intrarenal drug precipitation was significantly lowered when the mixture was used. In vitro antibacterial studies showed that the effectiveness of the mixture corresponded closely to that obtained by the total amount of all of the sulfonamide drugs in the mixture.

In view of these observations, we decided to try a combination of sulfadiazine and sulfamerazine in patients who were admitted to Gallinger Municipal Hospital with the diagnosis of bacterial meningitis. It is the purpose of the present paper to compare the clinical results and the incidence of drug toxicity obtained under this regimen, which was begun in October 1944, with those obtained in previous studies in which sulfadiazine or sulfamerazine was used alone.

From the Infectious Disease Service and the George Washington Medical Division, Gallinger Municipal Hospital, and the Departments of Pediatrics and Medicine, George Washington University.

Dr. Jean J. Vivino, Dr. Jay A. Robinson, Dr. Mark H. Lepper and the members of the Pediatrics Service and Georgetown Medical Division cooperated in the completion of these studies; Miss Jean Rowe furnished technical assistance.

PLAN OF STUDY

The procedure for diagnosis and treatment was as follows: Every patient suspected of having meningitis was given a lumbar puncture immediately on arrival on the ward. The first few drops of cerebrospinal fluid were allowed to fall onto a sterile chocolate agar slant for culture, and later transfers were made to "tryptose"-phosphate or "tryptose"-phosphate-hemoglobin broth. The remainder of the spinal fluid withdrawn was examined promptly with respect to the number of kinds of leukocytes present. Smears of the centrifuged sediment were stained with methylene blue and Gram's stain. The number of micro-organisms seen on smear was reported as "rare," "few" or "many." Bacteria were reported as being "rare" when they could be demonstrated only after considerable search; "few" cocci were recorded when half of the fields contained no organisms and relatively few micro-organisms were present in any one field, and "many" cocci were recorded when at least one micro-organism was seen in many fields and several micro-organisms were seen in most fields. An attempt was made to type the meningococci, pneumococci and influenza bacilli by the Neufeld technic if the organisms were present in sufficient numbers. The protein content was estimated qualitatively by the method of Pandey⁴ and quantitatively by the method of Dennis and Ayer.⁵ The dextrose content was determined qualitatively by the five tube reduction method⁶ and quantitatively by the Benedict's modification of the Folin-Wu method.⁷ A blood culture was also obtained before treatment was begun.

In adults the initial oral dose was 4 Gm. each of sulfadiazine and sulfamerazine followed by maintenance doses of 1 Gm. of each every six hours. In the case of patients who were severely ill or unable to swallow, or those who were vomiting, the initial dose was the same as the oral dose, except that the sodium salt was given by the intravenous or subcutaneous route in a solution which was not more concentrated than 0.5 per cent. The maintenance parenteral dose in these patients was 1.5 Gm. of each drug subcutaneously every eight hours, dissolved in 500 to 1,000 cc. of isotonic solution of sodium chloride. In most patients in the present series, the initial dose and one or two subsequent doses were given intravenously.

Proportionally smaller doses were given to children, computed on the basis of 0.045 Gm. of each drug per pound (0.099 Gm. per kilogram) of body weight per day. The initial dose was one half of the total calculated twenty-four hour dose. Subsequent doses were one fourth of the twenty-four hour dose given at six hour intervals. Subcutaneous maintenance doses were one third of the daily dose and were given every eight hours. The drugs were administered until the patient was afebrile for at least seven days, unless there was some indication for stopping them sooner. In the group of patients with meningococcic meningitis in a previous series who received either sulfadiazine or sulfa-

merazine alone, the method of administration was similar to that described here, except that adults were given 6 Gm. of the sulfonamide compound as the initial dose, followed by 1 Gm. every four hours, while the doses for children were calculated on the basis of 0.065 Gm. per pound (0.143 per kilogram) of body weight per day. Thus, the doses used in the present series represent a 25 to 33 per cent increase over the doses previously employed.

The patients were followed carefully during the period of drug administration with hemograms and urinalyses and by frequent determinations of urea nitrogen and sulfonamide compounds in the blood. Renal complications were studied particularly as to the presence of renal colic, gross hematuria, oliguria, anuria, azotemia or any combination of these. To patients in whom these renal complications developed fluids were given liberally in amounts of 3,500 cc. per day combined with 15 to 18 Gm. of sodium bicarbonate in divided doses. Whether or not sulfonamide therapy was discontinued at that time depended on the patient's response to the treatment for the renal complication

he evaluated at this time since the results were essentially the same as those previously reported with the use of penicillin plus one of the sulfonamide compounds alone.*

RESULTS

The present series of 135 patients who received the combination of sulfadiazine and sulfamerazine includes 75 with meningococcic meningitis, 38 with pneumococcic meningitis and 22 with other types of meningeal infection. This latter group is comprised of 17 patients with pyogenic meningitis in whom the causative organism could not be identified, 2 with meningitis due to *Hemophilus influenzae*, 1 with meningitis due to *Escherichia coli* and 2 with meningitis due to an unidentified gram-negative bacillus.

In a previous study of 207 patients with meningococcic meningitis who received either sulfadiazine or sulfamerazine alone,¹¹ the following factors were considered to be of prognostic significance: the age of the patient and the presence and duration of coma or delirium. The number of micro-organisms in, and the dextrose content of, the initial specimen of cerebro-

and the need for further sulfonamide therapy. We did not consider the appearance of crystalluria or microscopic hematuria an indication for discontinuing sulfonamide therapy. When crystalluria was pronounced, or microscopic hematuria was found to be present, fluids were forced, but sodium bicarbonate was withheld in order to parallel the treatment, with respect to alkalization, given the patients previously treated with only one sulfonamide compound.

Follow-up lumbar punctures on patients with meningococcic meningitis were done on the second hospital day and again when discharge was contemplated. If the cell count had not returned to 30 cells per cubic millimeter, the punctures were repeated at weekly intervals, and the patient was not discharged until that number was reached. Additional lumbar punctures were done only if recovery was not progressing satisfactorily. Each specimen of spinal fluid was examined in the same manner as the specimen obtained initially.

Patients with pneumococcic meningitis received the same amount of sulfonamide drugs as did the patients with meningococcic meningitis, but were given penicillin both intramuscularly and intrathecally. The results of the treatment of pneumococcic meningitis with penicillin and the sulfonamide mixture will not

spinal fluid were found to be of significance in the presence of coma or delirium. In order to evaluate the relative effectiveness of the sulfonamide mixture and of sulfadiazine or sulfamerazine alone, we compared the severity of the infection in the two groups of patients, on the basis of the foregoing prognostic factors. This comparison is shown in table 1. It can be seen that the factors which make for a poor prognosis were present as frequently in the 75 patients treated with the combination of sulfadiazine and sulfamerazine as in the 207 patients treated with either of the drugs alone.

The efficacy of the various sulfonamide compounds in the treatment of meningococcic meningitis can be evaluated most accurately on the basis of the case fatality rate. For group A, this was 6.7 per cent as compared with 10.1 per cent for group B. The difference in these case-fatality rates was not of statistical significance when tested by the chi square method.⁸ The case fatality rate for group A, however, was no lower than that obtained for the group of patients

treated during 1944 with a single sulfonamide drug alone.

A comparison of the fatality rates in the two groups according to certain prognostic factors was also made in table 1. When two factors contributing to poor prognosis were combined, for instance old age and

in coma with a low level of dextrose in the spinal fluid the fatality rates were 11 and 26 per cent respectively. Thus it is evident that not only was the case-fatality rate lower for the entire group of patients treated with the combination of sulfonamide drugs but it was also lower in the group treated with the mixture of sulfadiazine and sulfamerazine when patients with the poorest prognoses were considered. The differences in these case-fatality rates, however, were not statistically significant.

The ages of 3 patients in group A who died were 65, 48 and 22 respectively; each had been comatose for twenty-four hours prior to admission, and the spinal fluids of all 3 had many micro-organisms and a low dextrose content. Two other patients died from a fulminating infection characteristic of the Waterhouse-Friederichsen syndrome.

The clinical course of the disease in the patients who recovered, however, was not significantly altered by the use of the combination of sulfadiazine and sulfamerazine when one considers that the average duration of fever and pleocytosis of the cerebrospinal fluid in patients of group A was 3 and 16.7 days respectively, whereas in group B the figures were 2.5 and 19 days respectively.

In table 1 is shown the incidence of complications related to the meningococcal infection, 14 per cent in group A and 26 per cent in group B. In group A, there were 4 patients with polyarthritis, 3 with sixth nerve palsy, 2 with eighth nerve deafness and 1 with

optic atrophy. Among the patients in group B, the most frequent complications related to the infection were nerve palsies. These occurred in 35 patients. The other complications encountered were 10 instances of polyarthritis and 4 of purulent conjunctivitis.

The meningococcus was identified from the blood or spinal fluid in 51 patients in group A. Of these patients, 78 per cent had group I and 22 per cent group II (a) infections respectively.

TOXICITY OF THE SULFONAMIDE COMPOUNDS

Estimations of the sulfonamide concentration in the blood (sulfadiazine being employed as the standard) were made frequently in the case of 88 of the patients who were given the combination sulfadiazine and sulfamerazine, and the highest and lowest concentrations were tabulated for each patient. The values observed were found to be similar regardless of the type of meningeal infection. We therefore are comparing the average high, low and median sulfonamide concentrations in the blood obtained from these 88 patients with those obtained from 34 and 23 patients who received either sulfadiazine or sulfamerazine alone respectively. These figures are shown in table 2. It is apparent that the average sulfonamide concentration in the blood

in the group treated with sulfadiazine and sulfamerazine was slightly higher than those obtained in the sulfamerazine-treated group and much higher than those in the sulfadiazine-treated group.

In table 3 is presented the incidence of toxic reactions which occurred in 108 patients who received sulfadiazine and sulfamerazine in combination as compared with 99 patients who were given sulfadiazine alone and 87 patients who received sulfamerazine alone. The patients who died are not considered in this part of the toxicity study, since death often occurred before toxic reactions had time to develop.

The incidence of renal complications in the 108 patients with meningococcal meningitis who received the mixture of sulfadiazine and sulfamerazine was 7.4 per cent as compared with an incidence of 8.1 per cent and 11.5 per cent in the 99 and 87 patients respectively who received either sulfadiazine or sulfamerazine. The differences between these figures were tested by the chi square method and found not to be statistically significant.

On the other hand, the occurrence of fever, rash and conjunctivitis was greater in those patients who received the drug combination (15.7 per cent) than in those who received either sulfadiazine (10.1 per cent) or sulfamerazine (5.8 per cent). When these results were tested by the chi square method, it was found that the more frequent occurrence of fever, rash and conjunctivitis in the group of patients who received a combination of sulfadiazine and sulfamerazine approached

statistical significance when compared with those which occurred in the group of 186 patients who received either sulfadiazine or sulfamerazine alone.¹⁰

The hematologic (leukopenia and anemia) and gastrointestinal (nausea and vomiting) manifestations of drug toxicity did not occur frequently enough in any of the groups studied to be evaluated adequately. Furthermore, the significance of nausea and vomiting was especially difficult to evaluate since these symptoms were more often related to the disease than to the treatment.

COMMENT

Several investigators have indicated that the administration of two sulfonamide drugs in combination would prove to have several advantages over the use of one drug alone. We administered a combination of sulfadiazine and sulfamerazine to a group of patients with bacterial meningitis to ascertain whether there were any advantages to this method of sulfonamide therapy.

Among the 75 patients with meningococcal meningitis treated with the sulfonamide mixture, the case-fatality rate was 6.7 per cent, compared with a fatality rate of 10.1 per cent in a similar group of patients treated with either drug alone. No importance can be attached to this slight difference in fatality rates for two reasons: (1) The difference was not statistically significant when tested by the chi square method, and (2) the patients in the present series were treated at the end of an epidemic. The case-fatality rates for patients with meningococcal meningitis treated with sulfonamide compounds in this hospital have been reported previously.¹¹ In 1942, 48 patients were treated with a fatality rate of 12.5 per cent. For 1943, the corresponding figures were 107 patients and 12.1 per cent, and for 1944, 61 patients and 6.5 per cent. All of the foregoing patients received either sulfadiazine or sulfamerazine alone. The fatality rate of 6.7 per cent for the present series is comparable to that observed in the other cases treated in the latter half of the epidemic.

Although we were previously of the opinion that high sulfonamide concentrations in the blood bore no direct relation to recovery in patients with meningococcal meningitis,¹² we purposely used larger doses of the mixture of sulfadiazine and sulfamerazine in the present series than are ordinarily employed for two reasons, (1) to determine whether the better clinical results predicted by the proponents of the use of the mixture could be obtained with higher doses and (2) to explore the upper limits of dosage at which the mixture could be safely administered. The fact that the incidence of renal complications in the patients receiving these higher doses of the sulfadiazine-sulfamerazine combination was no greater than that observed in patients receiving the conventional doses of either sulfadiazine or sulfamerazine alone is in all probability due to the improvement in solubility gained by using a mixture of sulfonamide compounds. The incidence of renal complications might have been decreased further had we used a lower dose of sulfamerazine in proportion to the amount of sulfadiazine in the mixture, as did Frisk and his associates¹³ in their experiments. They found that when doses of

0.6 Gm. per kilogram each of sulfathiazole, sulfadiazine and sulfamerazine were administered to rabbits the last drug caused more renal concretions than did the other two. Frisk attributed this result to the slow excretion of the sulfamerazine as compared with the more rapid excretion of the other sulfonamide derivatives. Dowling, Lepper and co-workers¹⁴ have also shown that sulfamerazine in comparable doses causes a higher incidence of renal complications.

The recent work of Nilzen¹⁵ demonstrated the clinical efficacy of sulfonamide mixtures. Using the mixture, suggested by Frisk, which contained 0.37 Gm. of sulfathiazole, 0.37 Gm. of sulfadiazine and 0.26 Gm. of sulfamerazine per gram of final mixture, Nilzen treated 105 patients with gonorrhea with 9 Gm. daily for three days without the occurrence of any renal complications. Lehr¹⁶ also has published the results obtained by him in the clinical evaluation of a sulfonamide mixture. He treated 57 patients with a mixture of equal parts of sulfathiazole and sulfadiazine. The mixture was administered orally in doses of 4 Gm. initially and 1 Gm. every four hours thereafter. One gram every six hours was given when the severity of the disease being treated permitted smaller doses. The average duration of therapy was approximately five days. No renal complications occurred in any of his patients and in only 1 patient did drug fever develop.

That the incidence of fever, rash and conjunctivitis was significantly higher in our patients who received the drug mixture than in those who were treated with the individual drugs is worthy of comment. In a previous study, one of us¹⁷ treated 61 patients with pneumonia with a combination of sulfathiazole and sulfadiazine in doses of 0.25 Gm. of each every four hours. The incidence of fever, rash and conjunctivitis in these patients was 8.2 per cent as compared with 1 per cent in 140 patients who received sulfadiazine in doses of 3 Gm. per day. This is a statistically significant difference.¹⁸ No renal complications occurred in either group. Although we have no figures on the incidence of febrile and cutaneous manifestations in patients who received sulfathiazole alone in low doses, Dowling and Lepper¹⁷ found that among 321 patients who received sulfathiazole in doses of 1 Gm. every four hours, 6.2 per cent had fever, rash and conjunctivitis. These figures apparently confirm the fact that when two sulfonamide compounds are administered in combination the incidence of these complications is likely to be higher than when either drug is given alone.

This increase in the incidence of allergic manifestations which we have observed after the use of sulfonamide combinations may assume clinical importance in the light of recent pathologic reports on the occurrence of diffuse necrotic, granulomatous, polyvascular inflammatory and degenerative lesions in patients who received a sulfonamide drug prior to death.¹⁸ Such

lesions were felt to be definite allergic manifestations to the sulfonamide compounds. It should be remembered also that when sulfonamide mixtures are used there is an added disadvantage of possibly sensitizing the patient to more than one of the sulfonamide drugs.

There is some evidence that in pneumococcic pneumonia large doses of sulfadiazine will reduce the case-fatality rate below that obtained when the conventional doses are used.¹⁹ We are not aware, however, of any studies in which two different dosage regimens were compared in the treatment of meningococcic meningitis. Reinhold and his co-workers²⁰ studied concentrations of sulfamerazine in the body fluids of patients with meningococcic meningitis and found that for each milligram of increase in plasma sulfamerazine concentration the average patient response was found to be shortened by one day. Thus, higher plasma concentrations of this sulfonamide compound apparently lowered the morbidity resulting from the disease. On the other hand, in our previous study¹⁹ there was no evidence that high sulfonamide concentrations in the blood were accompanied by a higher recovery rate. When we compared the case-fatality rates, duration of illness and evidence of complications in our patients who received 6 Gm. of sulfadiazine or sulfamerazine with the same factors in the patients who received a combination of the two drugs, totaling a 25 per cent increase in dose, there were no significant differences between the two groups. It is possible that if higher doses had been given to the patients in the one group, the mortality and morbidity would have been lowered significantly. On the other hand, we found that even with this moderate increase in dosage, the use of the combination of the two sulfonamide compounds did not lower the incidence of the serious renal complications of sulfonamide therapy. It is to be anticipated that a further increase, let us say 100 per cent, in the dose of sulfonamide compounds would be attended by a prohibitive number of renal complications. Furthermore, the addition of a second sulfonamide compound materially increased the percentage of patients who had drug fever, dermatitis and conjunctivitis. We are consequently doubtful whether the advantages which may be gained by the use of mixtures of sulfonamide compounds are sufficient to outweigh the disadvantages of this procedure.

SUMMARY AND CONCLUSION

A group of 135 patients with meningitis, 75 with meningococcic, 38 with pneumococcic and 22 with other types of bacterial meningitis, were treated with a combination of sulfadiazine and sulfamerazine, a dose of 4 Gm. per day of each sulfonamide compound being used.

The case-fatality rate was 10.1 per cent in the patients treated with sulfadiazine or sulfamerazine alone and 6.7 per cent in the patients treated with a combination of the two drugs. This difference was not considered to be significant in view of the fact that the patients who received the combined therapy were treated at the end of an epidemic.

The incidence of renal complications occurring in the group of patients who received the mixture of sulfonamide compounds was 7.4 per cent as compared with an incidence of 8.1 per cent and 11.5 per cent in the patients who received either sulfadiazine or sulfamerazine respectively. These differences were not statistically significant.

The incidence of fever, rash and conjunctivitis attributed to the use of the mixture of sulfadiazine and sulfamerazine was 15.7 per cent, an increase over the incidence obtained when the drugs were used alone.

It is concluded that in the doses employed for the treatment of meningococcic meningitis the disadvantages of using a mixture of sulfadiazine and sulfamerazine outweigh the advantages.

HYPOGENITALISM DURING THE USUAL TIME OF PUBERTY

LEWIS M. HURXTHAL, M.D.
Boston

The purpose of this communication is to define hypogenitalism; to evaluate its significance when present in a 13 or 14 year old boy; to suggest conservative methods in management, and to enumerate the possible outcomes in untreated cases.

DEFINITION AND MEASUREMENT

Hypogenitalism should mean a disproportionate smallness of the external genitalia in relation to somatic development. Up to the age of 11 or 12 the testes as well as the penis undergo little change in size.¹ The average volume displaced by the prepubescent testicle is around 2 cc., and it is approximately 1.7 cm. long and 0.8 cm. wide.² With puberty, the testes increase in size, but the difficulty is that many boys do not begin pubescence at 11 years of age despite the fact that the growth continues. The fact that 18 per cent of boys do not begin pubescence until the age of 14 or after, I feel certain, is not generally recognized or at least is frequently overlooked.³ At this age, therefore, if no evidence of sexual growth can be discovered, one is confronted with a problem which is not only common but at times difficult to solve.

In the fat boy even with beginning pubescence, the genitalia often appear small because they are partially submerged in adipose tissue (fig. 1). The size of the testes may be estimated not only by linear measurements but also by comparison with models of various volumes⁴ (fig. 2). To determine the volume the scrotal skin is drawn tightly over the testis and the comparison is made. Any testis which is approximately 2 cc. in volume before pubescence may be considered normal, but meniscule, that is, those well below the 2 cc. volume should be viewed with suspicion and regarded as instances of hypogenitalism. The chief exception to this statement is cryptorchidism, in which the penis may be of normal size (fig. 1 B).

FRÖHLICH'S AND OTHER DWARFING SYNDROMES

The fat pubescent or prepubescent boy is often labeled an example of Fröhlich's syndrome or adiposogenital dystrophy or is said to be of the Fröhlich type. There is still considerable confusion in the usage of the terms

Fig. 1.—A, normal, obese and early pubescent boy 12 years of age. The penis is obscured in adipose tissue. The testes are above normal 2 cc. volume, indicating early pubescence. The height is 61 inches (154.9 cm.), and the height age, 14. This cannot be considered hypogenitalism. B, prepubescent boy with apparent hypogenitalism. The penis appears small because of massive obesity (160 pounds [72.6 Kg.]). The testes are in the inguinal canal and estimated to be of 2 cc. volume. The age is 11 years; the height, 61½ inches (156.2 cm.), and the height age, 14; the bone age, 14. Administration of 10,000 units of chorionic hormone was followed by slight further descent of testes and progression in size thereafter. The outcome is favorable in view of continued progress. The height two years later was 65½ inches (164.4 cm.); the weight, 190 pounds (86.2 Kg.). This is not Fröhlich's syndrome. Follicle-stimulating hormone was positive, estimated at 20 to 30 mouse units before therapy.

Fröhlich's syndrome, adiposogenital dystrophy and infantilism. When Fröhlich⁵ first described the syndrome, his patient was not obese but dwarfed, with proportionate retardation of sexual development (fig. 3). At a later date, his patient became rather obese, the latter being attributed to hypothalamic involvement from extension of a suprasellar cyst. Bartels⁶ introduced the term adiposogenital dystrophy, and also pre-

Fig. 2.—Models used for estimation of testicular size. The smallest represents 2 cc. volume, which is normal until pubescence. The largest volume, 18 cc., is usually found in a normal 18 year old boy or over. The intermediate models represent growth from the beginning of pubescence until its termination.

sented a dwarfed, obese person with proportionate genital retardation. Levi,⁷ in describing the syndrome

now known as Lorain-Levi infantilism, was also dealing with dwarfism and retarded sexual development in females. In all 3 instances, either a pituitary tumor or suprasellar cyst was present. These terms are essentially synonymous and the conditions are characterized, eventually at least, by retarded growth. There may be difficulty in some instances in determining whether or not dwarfing is present, but as a rule such is usually established by the time that advice is sought. Family heights must be considered in this investigation and school records obtained to determine the trend in recent months or years. Some allowance must also be made for the failure of puberal growth.

The time of onset of retarded growth as well as its duration may contribute to the size of the genitalia in these syndromes, since actual regression may take place despite a small increment of linear growth, especially in the late teens.

There are other dwarfing syndromes which have retarded genital development besides those already mentioned. These have characteristic and specific clinical features which make them, as a rule, readily recognizable. The more common are: cretinism, mongolism, Lawrence-Moon-Biedl syndrome and dwarfism such as is found in diabetes mellitus, various nutritional disorders and cerebral injury.

In all the dwarfing syndromes there is usually no hypogenitalism but only a retardation of genital growth which parallels somatic development. In fact, the testes may be larger in some dwarfs than those found in perfectly normal boys with somewhat late pubescence (fig. 4A). In such cases it is likely that the dwarfing condition began after the testes had reached the size observed, thus suggesting an arrest rather than failure of development.

Fig. 3.—Fröhlich's original patient.⁵ Note that the genitalia are proportionate to the size of the body.

CRYPTORCHIDISM

Cryptorchidism may be found in dwarfism (fig. 4B) or in an otherwise normal person without a disproportionately small penis or retardation of pubescence. Congenital absence of the testes (fig. 5), which is rare, must be considered in all cryptorchids, and can be suspected at the age of 13 or 14 because the penis remains abnormally small and does not respond to chorionic hormone therapy. Unsuccessful surgical treatment for cryptorchids may be followed by the equivalent of castration and hypogenitalism.

It is not my object to deal here with those conditions in which dwarfing occurs. It is not to be implied

that there always exists a sharp distinction between dwarfing and nondwarfing syndromes; however, for clinical purposes this distinction provides a practical rule of thumb. Fröhlich's syndrome, adiposogenital dystrophy and Lorain-Levi infantilism represent a pan-hypopituitarism or a situation in which at least growth

Fig. 4.—A, dwarf with proportionate genital retardation but not hypogenitalism. His age was 18; his height, 54 inches (137.2 cm.); his bone age, 10 years; his height age, 11 years. Urinary follicle-stimulating hormone was negative (less than 10 to 12 mouse units). There was 2 mg. of 17-ketosteroids per twenty-four hours; adrenal water test elicited a positive reaction. The sella turcica was normal. This case may be classified as Lorain-Levi infantilism or Fröhlich's syndrome. B, Fröhlich's syndrome, craniopharyngioma. The subject was a male 18 years old. His height was 56 inches (142.2 cm.) and his height age 11; his bone age was 11. There had been a previous operation for cryptorchidism before his condition was recognized. The penis was not out of proportion to the somatic age (11). The testes were meniscus.

and gonadotropic hormones are involved. Evidence of thyroid and adrenal deficiency and carbohydrate disturbance may be demonstrated in some (fig. 4A). Much more frequent and less complicated are those cases in which only the gonads or the pituitary gonad relationship appears to be affected. It is this group which I shall discuss in more detail.

DELAYED PUBESCENCE AND EUNUCHOIDISM

Boys of 14 years of age, for example, may show a rather wide range of skeletal maturation, which as a rule goes hand in hand with genital development.⁸ Obese boys of 14 with retarded pubescence need not be mistaken for examples of Fröhlich's or other syndromes, for they are generally well above average height. This fact alone is of great importance clinically because it practically limits the problem to deciding whether one is dealing with delayed pubescence or early eunuchoidism. The consistency of the testes may help differentiate between the two. I have already

referred to the suspicion that should be raised in connection with meniscus testes, but should they also be mushy in consistency, the chances for future function are greatly decreased. If, on the other hand, the testes are fairly firm but have not progressed beyond the prepubescent or pubescent size, it is impossible to predict the outcome, but spontaneous development is probable. One should, therefore, not jump to the conclusion at this age that a eunuchoid person is in the making; yet this is a serious threat and, if it could be predicted, would certainly demand treatment.

What observations, therefore, can be made to determine the probable outcome without therapy?

PUBESCENT BREAST ENLARGEMENT

Breast enlargement in the fat boy may be due only to adipose tissue and is unimportant as a diagnostic aid, but in the nonobese child, this is a fairly reliable sign of pubescence (fig. 6). This enlargement of the breasts subsides spontaneously, but if it persists while secondary sexual development occurs, another endocrine complex, gynecomastia with aspermia, must be suspected (figs. 10 to 13B).

Fig. 5.—Eunuchoidism with hypogenitalism and probable absence of testes. The subject was a male aged 38; his height was 72 inches (182.9 cm.) and his span, 75 inches (190.5 cm.); the epiphyses of the hand and wrist were closed but the iliac crests were open. Initial urinary 17-ketosteroids were 45 mg. per twenty-four hours. Urinary follicle-stimulating hormone was strongly positive on repeated tests. Note the pubic hair. There was good response to testosterone, with marked increase in size of penis and further growth of pubic and body hair. Excess 17-ketosteroids probably originated in adrenal cortex.

TESTICULAR BIOPSY

Testicular biopsy is not often performed on boys at the age of 14 or 15, probably because the tendency is to let nature take its course. Testicular biopsy may,

however, provide an immediate and definite recognition of primary testicular disease. In general, biopsies may reveal three types of abnormalities: The first is an immature testis or a state of testicular arrest (fig. 7). Such a finding suggests gonadotropic failure or delay and should lend a favorable aspect to complete genital development including spermatogenesis even without therapy. The second general type of abnormality to be found in testicular biopsy is the presence of variable degrees of sclerosis (fig. 8), tubular hyalinization or atrophy (fig. 9). Leydig cells may be few or absent. In the third type the interstitial cells may be normal and clumped (fig. 10), in which case there may be varying degrees of genital development.⁸ When the tubules are completely devoid of spermatogonia and only Sertoli's cells remain, the outcome is unfavorable as regards spermatogenesis. If Leydig cells also are absent along with tubular degeneration, the only hope for permanent primary and secondary sexual development without spermatogenesis is continued testosterone therapy.

Fig. 6.—Enlarged breasts of normal pubescence. The subject was a male aged 13; his height was 64½ inches (163.8 cm.) and his span 66 inches (167.6 cm.). His bone age was 12.9; his height age, 15. Urinary follicle-stimulating hormone was negative. There was 16.8 mg. of 17-ketosteroids per twenty-four hours. Note absence of pigmented areolas (compare with fig. 13 B). The testes were normal for his age. There was subsequent normal development with disappearance of breast enlargement.

URINARY GONADOTROPINS

The testes are thought to be dependent on two pituitary gonadotropic hormones. The first, entitled follicle-stimulating hormone, acts on the tubules; the second, luteinizing hormone, affects the Leydig or interstitial cells. Spermatogenesis, therefore, cannot take place without Leydig cell function so that the two hormones must be present to produce normal sexual function and development.

This hypothesis may be challenged by the work of Simpson and Evans,⁹ who found experimentally that luteinizing hormone (also called interstitial cell-stimulating hormone) will stimulate testicular tubules with amounts that do not visibly affect Leydig cells and will maintain secondary sex changes ordinarily created by Leydig cell secretion. Testosterone, too, was found by these authors to stimulate tubules in hypophysectomized rats; the effect on secondary sex characteristics was in proportion to the effect on the tubules. Implantation of pellets¹⁰ in the scrotum has also been shown to stimulate spermatogenesis, showing a pronounced

local effect. As long ago as 1938 Nelson and Merckel¹¹ pointed out that the capacity of steroids to maintain spermatogenesis was not dependent on their androgenic character and that steroids with low androgenicity, such as androstenedione or androstenedione, were more effective in maintaining spermatogenesis. So far as I am aware, reports of the clinical use of these for this purpose have not been published.

A finding of increased follicle-stimulating hormone is the rule with primary testicular disease or castration. McCullagh,¹² nevertheless, has shown in boys with delayed puberty and apparent hypogonadism that normal or increased amounts of gonadotropins may be found. However, since the test is primarily for the tubule-stimulating hormone—that is to say follicle-stimulating hormone—it cannot indicate the status of the interstitial cell-stimulating hormone (luteinizing hormone) of the pituitary. These patients may respond to

Fig. 7.—Hypoplasia of testes. The subject was a man of 20 whose condition probably represents arrested development occurring at the ages of 15 or 16. There was spermatogonia without maturation. Slight thickening of lamina propria was observed. No definite Leydig cells were seen. Clusters of black-staining cells are erythrocytes. There was subsequent development of spermatogenesis (fig. 14).

chorionic gonadotropins, or puberty may later spontaneously develop (fig. 1 B). Such behavior suggests that

12. McCullagh, E. P., and Kline, I. T.: Absence of Pituitary Failure in Fat Boys with Testicular Deficiency, *Cleveland Clin. Quart.* 13: 10-17 (Jan.) 1946.

either the testicle has to reach a certain degree of maturity for adequate response to normal quantities of luteinizing hormone or that luteinizing hormone is as yet insufficiently produced.

The opossum, which spends a large part of the usual embryonic life externally, does not react to gonadotropins until a certain developmental stage has been reached.¹³ This is also apparently true of the ovaries of all mammals after birth.¹⁴ The fact that some pre-pubescent boys do not respond to chorionic hormone while others do would appear to be in agreement with these observations, although testicular biopsies would be necessary for proof (fig. 11). Normal or moderately increased quantities of urinary follicle-stimulating hormone do not imply that the testicles are not responsive, but more likely indicate formation of insufficient luteinizing hormone to condition the tubules for utilization of follicle-stimulating hormone (fig. 1B). When present in great excess there is reason to suspect primary testicular disease such as found in surgical castrates or anorchi, but there are little data in the literature to indicate at what age this may first occur. It would seem that considerable variation is likely,

be in accord with the stage of somatic development. Thus the use of these determinations at the age under consideration may be of little aid.

URINARY 17-KETOSTEROIDS

Determination of urinary 17-ketosteroids at this age, too, is of doubtful value in distinguishing between delayed puberty and true eunuchoidism, for the values

Fig. 8.—Atrophy and sclerosis of testes in male eunuchoidism. Only a few spermatogonia and Sertoli's cells are present. There is increased collagenous tissue about tubules. No Leydig cells are visible. The specimen is from a male aged 31. The urinary follicle-stimulating hormone was weakly positive (estimated 10 to 20 mouse units); urinary 17-ketosteroids were 8.8 mg. per twenty-four hours.

just as in the variation of onset of normal puberty. Normal or decreased quantities may only indicate or

Fig. 9.—Atrophy of testes. Hypopituitarism due to chromophobe tumor. Autopsy specimen. Note absence of Sertoli's cells as well as spermatogonia and absence of Leydig cells. There is little or no fibrosis.

obtained in both should be at prepubescent levels.³ Rarely, in true eunuchoidism of testicular origin, they may be increased, probably due to adrenal hyperplasia (fig. 5). Such cases are always associated with excessive urinary gonadotropins.

BONE AGE

Roentgenograms of the hand and wrist or other joints may be of little value at this critical age.³ The variation from chronologic age in the normal may be from one to two years in contrast to the dwarfing syndromes in which bone age may lag far behind not only the chronologic age but also the height age (fig. 4). When eunuchoid persons have reached the age of 18 or 20, the epiphyses are usually still open, but the variation is too great at the age of 14 or so to be of decided value in differentiating true eunuchoidism from delayed pubescence.

TREATMENT WITHOUT BIOPSY

If a biopsy is not advisable, there are three courses which one can pursue: first, watchful waiting until the age of 15 or possibly 16 (fig. 12). By this time

13. Moore, C. R.: Sex Endocrines in Development and Prepuberal Life. *J. Clin. Endocrinol.* 4: 135-141 (March) 1944.

14. Hisaw, F. L.: Development of the Graafian Follicle and Ovulation. *Physiol. Rev.* 27: 95-120 (Jan.) 1947.

pubescence may have begun and, if not, the probability of spontaneous development decreases as time elapses. The objection to this policy is a social one which arises from the boy's embarrassment about his condition. Secondly, a trial of chorionic gonadotropin in doses of 500 to 1,000 units three times a week may be carried out. This may be followed by an increase in testicular size, the number of erections and, if continued long enough, other signs of pubescence. If there is evidence of stimulation after one or possibly two months, the treatment should be discontinued temporarily to see whether spontaneous progression occurs; if not, one can again proceed with chorionic gonadotropin, but testosterone is far more practical. A third form of therapy is oral administration of testosterone in small doses of not over 20 to 30 mg. a day. With primary Leydig cell failure, this may considerably increase the size of the testes, providing that extensive tubular degeneration is not present (fig. 11). This medication, too, may be prescribed for a few months only and discontinued in the hope of unaided progress. If such does not occur, it is probable that testosterone will have to be used indefinitely.

Fig. 10.—Tubular hyalinization with clumping of Leydig cells. From a case of gynecomastia and aspermia. Secondary sex development was normal, with ejaculation and libido. A few tubules remain, showing early atrophy and Sertoli's cells. Urinary follicle-stimulating hormone was strongly positive. There was 15 mg. of 17-ketosteroids per twenty-four hours (fig. 13 B).

OUTCOME OF CASES WITHOUT TREATMENT

There are three well known body types which may result from delay or failure of pubescence if untreated. The first is that of the boy who eventually matures. There may be slight eunuchoid skeletal proportions, but for all practical purposes these persons appear

normal when fully matured. The second is that of the typical eunuchoid with hypogenitalism and eunuchoid skeletal proportions, namely long arms and legs (fig. 13 A). When eunuchoidism is due to primary testicular failure there is occasionally more body and sexual hair and less skeletal change. The third is the person with gynecomastia and varying degree of eunuchoidal changes (fig. 13 B). Gynecomastia in

Fig. 11.—Hypogenitalism responding to testosterone. A, 14-year-old boy after one year of unsuccessful therapy with chorionic hormone, 1,000 units weekly (question of sufficient quantity). His height was 60¾ inches (154.3 cm.); his height age, 14 years; his weight was 170 pounds (77.1 Kg.); his bone age, 14; urinary 17-ketosteroids, 3.4 mg. in twenty-four hours; urinary follicle-stimulating hormone was negative on two occasions. The volume of the testes was less than 2 cc. Unsuccessful attempts were made to diet for weight reduction for three months; meanwhile there was growth of ¾ inch (1.9 cm.). B, after twenty-five days of methyl testosterone therapy, 30 mg. per day. The volume of the testes increased to 5 cc. The outcome is uncertain, but therapy is to be discontinued in hope of spontaneous progress.

these persons is probably dependent on the amount of Leydig cell function, because it parallels secondary sexual development.¹⁵ Aspermia is present due to tubular hyalinization, at least late in the disorder. The breasts show well marked and pigmented areolas.

TREATMENT

Treatment of the late pubescent boy is unnecessary unless he is obese. In fact, careful dieting is thought to hasten genital development. One must make certain when such a person is seen for the first time that sexual development is taking place in order to exclude arrest, which is possible at any age.

In persons eunuchoid because of primary testicular failure, testosterone in some form should be given as

15. Heller, C. G., and Nelson, W. O.: Hyalinization of Seminiferous Tubules Associated with Normal or Failing Leydig Cell Function: Discussion of Relationship to Eunuchoidism, Gynecomastia, Elevated Gonadotrophins, Depressed 17-Ketosteroids and Estrogens, *J. Clin. Endocrinol.* 5:1-12 (Jan.) 1945.

early as possible because of the physical as well as psychic handicap.

It is well known that the majority of these persons respond to testosterone with the development of secondary sex characteristics. The occurrence of spermatogenesis, however, is exceedingly rare. In cases of eunuchoidism or genital arrest beginning during the puberal period and reaching the age of 18 or even later, and with the testes of fairly good size and consistency, there is a chance of maturation of spermatozoa if tubular degeneration has not proceeded too far (fig. 14). I have observed a number of such cases.¹⁶ The urinary follicle-stimulating hormone in these cases has not been in excess. I have presumed that in those cases in which there has been response and in which biopsy was not performed there has been immaturity of the testes possibly based on luteinizing hormone or Leydig cell deficiency rather than absence of these hormones.

The causes of tubular degeneration are numerous and in many instances unknown. It is rather probable that hormonal failure either of the pituitary or of the Leydig cells is a cause of such degeneration. Evidence for this exists in the hyaline degenerative changes seen in the testes of persons with caromphobe tumors when a high degree of hormonal deficiency exists (fig. 9). It is reasonable to assume, therefore, that if these deficiencies can be corrected by early therapy, the chance for preventing irreversible changes and aspermatogenesis might be reduced. For this reason, testicular biopsy should be carried out more frequently in such cases in the puberal period to assess this possibility properly. Large doses of testosterone are assumed to depress testicular function,¹⁷ and although the evidence for permanent damage is not convincing, such doses should be avoided for the present. The possibility that smaller doses of testosterone or methyl testosterone may act through the pituitary has not been clearly established, but it is possible

Fig. 12.—A, delayed puberty with beginning pubescence. Boy, aged 16; bone age, 14; height age, 14. Genitalia are proportionate to somatic development and cannot be considered example of hypogenitalism. Pubescence has begun. Normal development followed without therapy. At this age this might represent arrest, but school records and six months' observation demonstrated normal progress, although delayed.

that they may do so. Heller and Nelson¹⁸ reported a suppression of urinary gonadotropins with testosterone propionate but not with free testosterone implanted as

pellets. This difference as well as the effect of the less androgenic steroids in maintaining spermatogenesis in animals illustrates the complexity of the problem and demonstrates that there is still much to be learned.

SUMMARY AND CONCLUSIONS

The term hypogenitalism has been defined and its relation to the normal individual of prepubescent or pubescent age has been reviewed. For purposes of clinical recognition it has been pointed out that the establishment of retarded growth is of prime importance in distinguishing Fröhlich's syndrome, adiposogenital dystrophy syndrome and infantilism from delayed puberty or beginning eunuchoidism. The latter apparently involves only the testes or the pituitary gonadal relationship.

Fig. 13.—A, eunuchoidism with hypogenitalism. Male, aged 24; height, 72½ inches (183.2 cm.); span, 74½ inches (188.9 cm.). The testes were "small." The urinary follicle-stimulating hormone was negative. Urinary 17-ketosteroids were 8.1 mg. per twenty-four hours. Bone age was 15. No treatment was given until age 33, at which time his condition remained essentially the same. Methyl testosterone and testosterone propionate were used for over a year with good results. Five months after cessation of therapy a biopsy showed no Leydig cells, no peritubular sclerosis. Tubules showed spermatogonia and possibly a few spermatozoa. An ejaculated specimen showed no spermatozoa. The volume of the testes was 5 cc. (This case as well as others of the same type will be the subject of a later report.) B, gynecomastia and aspermia. The subject, aged 23, had had enlarged breasts all his life. Puberty had developed at 12, voice change at 15 and he had shaved at 17. There were normal libido and ejaculation. There were no eunuchoid changes. The patient received "arm and hip injections which increased chest and pubic hair but had no effect on genitalia or breasts." Urinary follicle-stimulating hormone was strongly positive. There was 16.4 mg. of 17-ketosteroids per twenty-four hours. There were no spermatozoa. The testes were atrophic, not over 5 cc. in volume, of mushy consistency. Figure 10 shows a photomicrograph of a similar case.

Testicular biopsy may provide immediate recognition of primary testicular failure as opposed to a theoretic selective failure of gonadotropin (luteinizing

hormone). Since spermatogenesis and development of secondary sex characteristics have been accomplished by the use of testosterone in hypoplastic testes without severe degenerative changes, a plea is made for earlier diagnosis and treatment in cases of this type. It is possible that failure of the Leydig cells contributes to the degeneration of the tubules in the testes in some cases of eunuchoidism or hypogonadism arising during adolescence.

Fig. 14.—Genital arrest with testicular hypoplasia. A, 18 year old boy with puberal arrest beginning at age 15 to 16. His height was 68 inches (172.7 cm.), and his span, 68 inches; his bone age was 15 years 3 months; the urinary follicle-stimulating hormone was negative. Urinary 17-ketosteroids were 7.8 to 7 mg. per twenty-four hours. Two years later his height was 69 inches (175.3 cm.), and his span, 71¼ inches (181 cm.). There had been no genital growth; the bone age was 16.3. Urinary output of 17-ketosteroids was 10.4 mg. per twenty-four hours. B, after four months' treatment. Chorionic hormone was administered for one month, which produced some genital growth and more frequent erections. Ejaculated specimen before injections showed no spermatozoa. After three months of oral administration of methyl testosterone, 30 mg. a day, further increase in genital growth was shown. There were 2 to 3 sperms per high power field in one month after chorionic hormone therapy; there were 1,500 per cubic centimeter after two months of methyl testosterone therapy. There were many abnormal forms. (Figure 7 shows photomicrograph of testicular biopsy specimen before treatment.)

ABSTRACT OF DISCUSSION

DR. WINGATE M. JOHNSON, Winston-Salem, N. C.: My discussion will be brief and more in the nature of questioning than of addition to what Dr. Hurxthal said in his excellent paper. It has been my experience that the Fröhlich syndrome is rare. I have had about the same experience with it that Dr. Alvarez has had with brucellosis. I looked for it for a long time, but so far it has been hard to find. I think that a great many fat boys are given that diagnosis erroneously. When a fat boy like the one whose picture you saw today, and whose testicles but not whose penis could be seen, appeared in the clinic of the late Dr. Holt, he would look at him and say,

"Well, that boy has an undescended penis." I should like to ask whether bilateral undescended testicles could contribute to hypogenitalism and at what stage of development Dr. Hurxthal would recommend operation, if necessary. He spoke of using gonadotropin followed by testosterone. I should like to ask whether he always uses gonadotropin first and then testosterone, and whether the effect of the testosterone is permanent or whether the treatment has to be continued indefinitely.

DR. LEWIS M. HURXTHAL, Boston: I purposely did not discuss cryptorchidism; ordinarily the penis is of normal size in cryptorchidism, but after unsuccessful operation, in which there may be interference with the blood supply, hypogenitalism may occur which is an actual hypogonadism. Cryptorchidism may occur in a true Fröhlich's syndrome, but the hypogenitalism is because of the latter and not cryptorchidism. In cryptorchids' secondary sex characteristics may develop and normal genitalia without descent of the testes, or with successful operation to bring the testes down. The time for operation for cryptorchidism is a much disputed point. Earlier in our experience we never did anything about it until the patient was 10 or 11 years of age. I think that children past the age of 6 may be given chorionic gonadotropins for a month or two, and if no result is obtained, I would favor surgical intervention then. Such treatment may assist the surgeon because it causes the testes to become firm and makes operation easier. In regard to giving gonadotropin and testosterone, I did not mean to say that both were given simultaneously. It is well to try oral administration of methyl testosterone if gonadotropins fail. Oral administration of testosterone may be tried first and will work in some cases, as I have shown. The result of treatment with either substance may be a coincidence, but in the majority it is the cause of descent. It is best to give testosterone orally, and I think that it is well to avoid large doses such as 50 or 75 mg. a day. There is no proof that large doses do any permanent damage, although they apparently do inhibit the pituitary, at least temporarily. The question as to the necessity of using testosterone permanently depends on whether or not the boy continues to have genital development when administration of testosterone is discontinued. If regression occurs, testicular biopsy is indicated. The advisability of the future use of testosterone propionate can then in all probability be determined.

Oliver Wendell Holmes.—Let me begin with my first experience as a medical student. I had come from the lessons of Judge Story and Mr. Ashmun in the Law School at Cambridge. I had been busy, more or less, with the pages of Blackstone and Chitty, and other textbooks of the first year of legal study. More or less, I say, but I am afraid it was less rather than more. For during that year I first tasted the intoxicating pleasure of authorship. A college periodical, conducted by friends of mine, still undergraduates, tempted me into print, and there is no form of lead poisoning which more rapidly and thoroughly pervades the blood and bones and marrow than that which reaches the young author through mental contact with typemetal. *Qui a bu, boboira*—he who has once been a drinker will drink again, says the French proverb. So the man or woman who has tasted type is sure to return to his old indulgence sooner or later. In that fatal year I had my first attack of author's lead-poisoning, and I have never got quite rid of it from that day to this. But for that I might have applied myself more diligently to my legal studies, and carried a green bag in place of a stethoscope and a thermometer up to the present day. What determined me to give up law and apply myself to medicine I can hardly say, but I had from the first looked upon that year's study as an experiment. At any rate, I made the change and soon found myself introduced to new scenes and new companionships.—Rosen, George, and Caspari-Rosen, Beate: 400 Years of a Doctor's Life, New York, Schuman's, 1947.

FOLLOW-UP OF MEDICAL RECOMMENDATIONS

Results of a Health Checkup of a Group of Well
Children in Chicago

MARTHA CRUMPTON HARDY, Ph.D.
Chicago

The need for medical services, other than for illnesses, by a large proportion of the child population has been well established through health surveys made in different sections of the country and has been dramatically emphasized by the number of selective service rejections during World War II. Although there is awareness of this problem, the task of getting defects corrected is a difficult one.

A report from one community with regard to the reasons for rejection for military service of their selectees has shown that the conditions for which the men were rejected had been noted fifteen years before in the records of their school health examinations. As the authors of this inquiry have stated: "It is particularly disturbing to find that in spite of knowing which children in a community would grow up into physically handicapped adulthood, the health professions, the lay professions, and especially society as a whole, have to date apparently failed to take full advantage of the knowledge."¹

Under the impetus of the war emergency a high percentage of corrections of defects among high school² and college³ students has been reported in connection with prehabilitation programs. The personal interest of these young persons in their fitness for military service was undoubtedly a strong motivating factor in these returns. There are no comparable figures for children, but from the past experience of school physicians and nurses it is questionable whether equally satisfactory results would have been achieved, even during the war years, with children.

For a number of years the Elizabeth McCormick Memorial Fund has been concerned with the follow-up by parents of recommendations made at the time of a health check-up of their children. Results from a recent investigation with families of low income bear directly on this question of the amount of remedial and preventive services preschool and school children actually receive.

A brief summary is here reported of the data from a follow-up of medical examinations of a group of 1,068 Chicago children representing 446 families. Examinations were made by the pediatric staff of the Elizabeth McCormick Memorial Fund between September 1942 and August 1943.

The inquiry was a part of a joint investigation conducted with the Aid to Dependent Children Service of the Cook County Bureau of Public Welfare regarding the community resources for meeting the health needs of children under the supervision of this welfare agency. The children were living with one or both parents or with a close relative who maintained a home for them. They were receiving grants as dependent children because they had been deprived of parental support or care by reason of death, continued absence from the

home or incapacity of either or both parents. In most of the cases the mother was in the home and the father was dead.

A small number of the families had their own physicians, but for the most part they had to rely on clinic facilities for whatever medical attention they received. Their average annual incomes were around \$1,100 (1942-1943).

The children were so-called well children, none of whom was under the supervision of a health agency or was registered at a clinic. They were selected from all areas of the city. An effort was made to have the racial distribution in each district correspond to that of the welfare caseload of that district.

No pressure was exerted to force the family to have the children examined. If the parent or guardian was interested in the health check-up, an appointment was scheduled. Examinations were always made in the presence of the adult who supervised the child's daily program—usually this was the mother.

Pertinent facts about the family were secured from the case worker prior to the date of the appointment, and further history concerning the health and development of the individual children was given by the mother when she appeared for the examination. The physician had an opportunity to read over this record before he saw the child. Young children and boys were examined without clothing. Older girls were stripped to the waist. Shoes and stockings were always removed.

The group participating in the study included 532 boys and 536 girls. Their average age was 10 years—20 per cent of them were between 2 and 6 years of age, and a like proportion had passed their twelfth birthday at the time of their health check-up. In most cases at least 2 children per family were examined, the average number being 2.4.

After the completion of the health check-up of a family group, the physician talked with the mother about the remedial care and immunizations which the children needed. Immediately after the medical conference a nutritionist conferred with the mother on plans to improve the family diet and other health habits. At this time the mother was given a written memorandum of the recommendations made by the physician and the nutritionist. She was also informed that her case worker would help her to arrange to obtain the advised health services.

Although the families included in this investigation were receiving financial assistance, there is no reason to assume that their attitudes toward health differ from those of other families of low income in the general population. They indicated their interest in the health of their children by bringing them to the examining center for a physical check-up. They were there made aware of the health needs of their children and were later given assistance in locating the proper facilities for the services advised. Under these conditions the facts with regard to the care actually secured for the children should be particularly revealing as to the problems which low-income families encounter in a follow-up of medical examinations of their children.

PLAN FOR FOLLOW-UP

In this inquiry the follow-up involved three procedures: to assist the family to plan ways and means of securing the advised health services; to check with them from time to time and to urge that appointments with physicians and with clinics be kept; and, finally, to check with the health agencies on the care actually

secured. Full responsibility for this part of the investigation was assumed by the Aid to Dependent Children Service. Visits to the homes of the children who required care were made by the case workers as soon as possible after a report of the physician's recommendations was received.

There were only 5 of the 446 families represented in the group examined that did not require some type of health service. Usually 2 or more children in each family needed attention for a number of different remediable conditions. The plan to obtain the required care depended on locating the proper health facilities and arranging for services within the framework set up by the community or the responsible agency for remedial and preventive services to families of low income.

During the years covered by this study—September 1942 to January 1946—changes in the size of the selected group would be expected. Some families moved away; others became completely self-supporting because of increased wages of the mother or other members of the family and consequently were no longer under the supervision of the agency; in others, the children who had been advised to have care were out of the home. No follow-up was possible in the case of 39

the mouth and teeth rather than on an examination by a dentist. Incidence under these conditions would no doubt be underestimated.

A summary of the professional services advised for these children is presented in table 1, for white and Negro children separately, in terms of the type of care recommended—medical, dental or immunization. The large majority of the children were in need of some type of health service—97 per cent. Medical attention was advised for 73 per cent (65 per cent of the white and 80 per cent of the Negro); dental services for 67 per cent (75 per cent of the white and 59 per cent of the Negro), and protection against either diphtheria or smallpox for 53 per cent (46 per cent of the white and 61 per cent of the Negro children).

The incidence of health problems among this group of dependent children appears to differ little from that noted in previous reports for other income groups. Comparative data are cited in table 1 from a marginal economic class, which includes families having annual incomes around \$1,200 in 1940 and from an economically independent class having incomes in the average or upper brackets—most of them ranging from \$2,000 to \$4,000. The results of the present investigation are in agreement with those of other studies⁴ in showing that

families, and 74 other families were lost before they had obtained any of the recommended services.

The follow-up records consist of progress reports submitted by the case workers and information obtained from clinics, private physicians and dentists and from the Chicago Health Department. Cumulative health service records are available for 789 children representing 328 families. These families were still under the supervision of the agency at the conclusion of the investigation or had carried through at least a part of the plan for care before their cases were closed. Their follow-up records extend over approximately two and a half years.

GENERAL TYPES OF HEALTH SERVICES ADVISED

The health services advised by the physician were for many different types of conditions. Remedial care was recommended in cases in which (1) specific conditions were judged to deviate from the normal to the extent that professional services were advisable or (2) symptoms or history indicated a need for further examination or treatment. Vaccination against smallpox was recommended in cases in which a scar was absent. Immunization against diphtheria was advised for young children who had never been given toxoid injections. The Schick test was advised for the older children who had no history of this protection and for those who had had none since infancy.

Recommendations for dental care were based on the judgment of a physician after a general inspection of

the majority of children regardless of the income level of the family are likely to be in need of medical attention.

Follow-up records on the health services obtained are available for 3 of every 4 of the selected Aid to Dependent Children group. Inspection of the second columns of the two sections of table 1 shows that the health needs of this "followed group" are representative of those of the total white and Negro groups examined. The remainder of this report will be concerned with the services secured for the 789 children included in the follow-up study.

The observations are organized around three major questions: (1) To what extent were the physician's recommendations regarding the individual child's needs carried out, (2) what effort was made by the family to secure the health services advised and (3) what reasons were given by the families for their failure to obtain the care recommended?

HEALTH SERVICES OBTAINED

Analyses of the records of the 789 children comprising the followed group indicate that attention to some of their needs was secured in the majority of cases but that less than one third of the children obtained all the care advised. "All care obtained" is here interpreted as services received and patient either discharged or continuing under professional care as instructed.

4. Hardy, M. C.; Boyle, H. H., and Newcomb, A. L.: Physical Fitness of Children from Different Economic Levels in Chicago, J. A. M. A. 117: 2154-2161 (Dec. 20) 1941.

Results as to the amount and type of professional services obtained for the children in this study are given in tables 2 and 3. A general summary of the data in terms of broad categories of the type of attention required is given in table 2. The categories refer to recommendations for medical care, dental care and immunizations. An over-all classification of professional health services is used to point up the amount of care secured, regardless of the type. Table 3 gives the results with respect to specific recommendations and shows whether or not an effort was made to obtain the needed services.

Care has been assumed when the records indicate that any part of the recommendations made by the examiner had been carried out. Services were considered as completed when care had been secured for all the conditions requiring attention or when care was in progress. Cases in which service was obtained (but not for all problems) or was incomplete were classified as "obtaining some care." This description

* Excluding orthodontia.

covers the following types of situations: (1) when correction or treatment was reported for one or more but not for all of the conditions requiring care; (2) when remedial services were begun but not continued, and (3) when further diagnosis was secured as advised, but the recommendations for treatment were not carried out. The classification of "no care obtained" includes, in addition to those who never reported for attention, cases in which the child left before the examination was completed and did not return and those in which the child failed to report to the special services to which he was directed by the clinic, e. g., eyes, orthopedic or surgery.

Reference to table 2 reveals that 75 per cent of this group of children secured at least a part of the care advised for them. In the two and a half year period covered by the follow-up study the recommendations for special health services were carried out fully, as here interpreted, for 38 per cent of the white children and 26 per cent of the Negro children. At the conclusion of the follow-up investigation there were still 69 per cent of the children who had some unmet health needs for which professional service had been recommended by the physician.

These unmet health needs were most often those requiring medical care. Comparative frequencies of the amount of care obtained indicate that: 37 per cent of the children needing medical care secured all that was advised; 51 per cent of those needing dental care received it; and 60 per cent of those advised to be immunized against certain diseases completed this service.

Whether or not recommendations for medical services were carried out appears to have been related to the type of medical attention needed. Services involving surgical intervention or treatment were less frequently completed than those in which further observation and diagnosis or preventive measures were recommended. It should be noted that surgical procedures and treatment are types of care which may necessitate repeated visits to the clinic or supervision over an extended period of time. The proportion of the recommendations for different types of medical services which were carried out fully was as follows: 64 per cent of the recommendations for preventive measures; 56 per cent of those for further diagnosis; 44 per cent of those for treatment, and 36 per cent of those for surgical care. A summary of these data is given in table 3 in terms of the attention received for specific recommendations: whether the patient secured the service and continued as instructed, discontinued before care was completed or did not attempt to obtain service.

Although the type of care needed was a factor in the completion of the recommended care, there was little indication that among the families in this study it had any influence in determining whether the child would be taken to a physician as advised. At least one visit was made to secure the medical attention recommended in the case of most of the conditions under each classification. Differences between the various types of medical services with respect to the family's attempt to obtain care were negligible in size.

Negro families were more likely to make some effort to secure the advised services than were the white families but were less likely to continue the service as instructed. A larger proportion of the Negro children than of the white children were taken at least once to a clinic or a physician's office for the attention recommended. Decided differences between the groups were noted for each type of medical service except that requiring treatment, in which case the same proportion of Negro and white children reported for care. However, fewer Negro than white children continued under care till the service was completed. The only type of care which the Negro children followed through to the extent that it was carried out by the white children was that for immunization.

Extent of Medical Care for Certain Health Problems

The most frequent specific problems noted by the physicians as requiring medical attention concerned tonsils, orthopedic abnormalities, eyes, conditions of the genitourinary system and of ears and skin. The incidence varied from 31 per cent in the case of tonsil conditions to 6 per cent for skin.

Either removal of the tonsils was definitely advised or their condition was noted for further observation in the case of a large number of the children. Most of these children so advised made one or more visits to a physician or to a clinic regarding this problem (71 per cent). Among those who reported for care, the need for removal was confirmed in 4 of 5 cases, according to the records at hand. Tonsillectomies were performed on 18 per cent of the children referred, and an additional

11 per cent were either under care preparatory to the operation or were on a waiting list for hospital admission at the conclusion of the follow-up. In 29 per cent of the cases, apparently no effort was made by the family to do anything about this recommendation of the examiner. It is highly probable that some of these families were discouraged from taking their children for tonsillectomies because they were aware of the long waiting lists of the clinics and hospitals, at that time. Then, too, shortly after the recommendations were made Chicago had an outbreak of poliomyelitis during which physicians advised that operations on the throat be delayed unless the condition was urgent.

The incidence of foot abnormalities ranked high among these children. Here, again, the need for correction was confirmed by later clinic examinations in

Signs of nutritional inadequacies were of frequent occurrence among these children, but relatively few children were considered to need special medical attention for the condition. Half of these obtained the care recommended for them, but more than a third of them failed to report for the service advised.

Care for an umbilical hernia was recommended for a number of the children in this study. At the time of the final records, 10 per cent of these children were receiving care, 16 per cent had been discharged as requiring no treatment and 42 per cent had failed to continue under care as instructed by the clinic. In a third of the cases this type of recommendation was entirely disregarded by the families.

There were 26 children in this follow-up study for whom in the judgment of the physician an examination

* Including orthodontia.

the case of the majority of those for whom the records are available, but only 20 per cent of these secured the service advised. A relatively large number of those who had foot abnormalities either failed to report at all or did not go to the orthopedic clinic as directed.

Other conditions for which orthopedic care was recommended concerned defects of the spine. Few cases were involved, but only half of the children received any attention—the others were never taken for care.

Recommendations for remedial services for eyes, ears and nose were based on inspection at the time of the examination—eyes by general inspection and ears and nose with an otoscope. Tests of visual acuity and of hearing were not made. Approximately 2 of 3 of those who were advised to have care received some attention. Most of the children who reported for further examination of the eyes and ears required corrective treatment.

by a heart specialist was indicated. The records show that 20 of these children reported for further diagnosis—13 were found to require special attention, but only 6 of these continued under medical supervision. In other words, 50 per cent of the children whose cardiac condition seemed questionable at the time of their general health checkup were later given a definite diagnosis of cardiac disease or were referred for more tests and observation before the final diagnosis. Half of these cardiac patients or suspects did not receive the professional attention recommended for them. Some of these children made several visits to the clinic but failed to keep later appointments as instructed. Others did not return after the diagnosis. Although the number of cases here involved is small, the problem is recognized as a serious one and hence implications of the observations on care received are considered to be particularly significant.

The fact that 23 per cent of the children who were referred to a cardiac clinic failed to go and an additional 27 per cent who were known to require supervision were not receiving it would certainly suggest a lack of understanding on the part of the parents of the importance of remedial services. If this large a proportion of the children who had a suspected cardiac involvement was without care, it is not surprising to find that many other conditions were neglected by the families.

The Number of Health Problems as a Factor in Medical Care Obtained

From the analyses of the cumulative health records of the children in this study there is evidence that the more conditions the physician cited as requiring medical attention the better the child's chances were of getting to a physician or a clinic. Children having only one type of health problem, regardless of the seriousness of the condition, were less likely to be taken for care than were those having three or more conditions for which care was advised. It is not unlikely that the mere fact that more time was required at the health check-up for the physician to interpret several recommendations to the mother served to stress the needs of these cases and impressed her with the importance of medical care for them. Relatively few children having as many as three conditions for correction or treatment failed to report for the advised services.

With respect to the completion of the services the situation was reversed. The child having only one or two health problems, if he received any medical attention, was more likely to have the recommended service completed than was the child who had many conditions for which care was advised. Children having many problems were more likely to discontinue the service before all the corrections had been completed than were those having few problems. In the order of the number of problems mentioned by the physician as requiring medical services, the figures show that 45 per cent of the children having one condition for care, 31 per cent of those having two conditions, 26 per cent of those having three conditions, and 15 per cent of those having four or more conditions continued under care until discharged. These successive differences are relatively small in some comparisons and are not all statistically significant, but they are consistent in direction and some of the differences are large.

The trend of these data is suggestive of the influence of the number of specific health problems indicated by the physician at the time of the examination in determining whether the recommended care will be obtained. These results clearly point to the need for increased emphasis on securing and maintaining the interest and full cooperation of the parents in whatever is advised for the children.

Dental Care Obtained

It was stated earlier in this report that the incidence of dental needs as given in this study is probably an underestimation of the extent of the dental problem among these dependent children, since examinations were not made by a dentist. Nevertheless, in the judgment of the physician most of the children were in need of dental care.

The sources of care used by the families, according to the reports at hand, were in the order of their frequency: clinics, dental services in public schools and private dentists. In planning with the family ways

and means to arrange for dental care the case workers recognized the lack of facilities for orthodontia that are available to families of low income and made no attempt to assist them in obtaining this type of care. Recommendations for orthodontia have, therefore, been eliminated from the analyses summarized in table 2. Observations on this problem are, however, included among the specific recommendations given in table 3.

In general the figures with respect to dental care obtained show a similar trend to those for medical services, although more of the children were reported to have completed the dental care than was the case with medical care. Reference to table 2 shows that more than half of the children who were advised to have dental care secured it and most of them completed the services, as here interpreted. Among the white children 56 per cent and among the Negro children 47 per cent were reported to have completed the recommended dental services, exclusive of orthodontia.

Carious teeth was the most frequent type of physical defect observed among these dependent children, as it has also been among other groups of children. Information on the extent of care received for this defect is given in table 3. The majority of the children with dental caries were taken to a dentist, and most of them completed the treatment. However, a large number of children who needed remedial care never reported for it.

Orthodontia was advised for 11 per cent of the children included in the follow-up study. In 23 cases—15 white children and 8 Negro children—this was the only dental need observed by the physician. Although no provision for this type of service was planned by the case workers, through special arrangements a few families were able to obtain care. Treatment was reported to be in progress for 8 children.

Immunization Obtained

Recommendations for immunization concerned the need for vaccination against smallpox and for protection against diphtheria—either toxoid or the Schick test as the history indicated. Of the health services advised for the children, these immunizations were the most readily and conveniently secured in Chicago. They were also one of the most difficult of the services to verify.

More than half the children included in this study were in need of one of these measures, and for approximately 1 of 4 of them both measures were recommended. The advised protection was obtained by 60 per cent of these subjects, and an additional 8 per cent received one of the two recommended immunizations—usually a diphtheria-preventive measure.

At the time of the health check-up a third of the group had not been successfully vaccinated against smallpox. In most of the cases vaccination had never been performed. From the follow-up records it is estimated that 64 per cent of those for whom vaccination against smallpox was recommended reported to a center for this protection. In most of these cases the reaction was said to be positive, but in a few cases the result was not known.

Protection against diphtheria was advised for 312 of the children. Of these, 70 per cent reported for immunization and most of them completed the necessary injections. However, 30 per cent of the children for whom either a Schick test or diphtheria toxoid had been recommended failed to report for these measures during the period covered by this study. This number included both preschool and school children.

As previously mentioned, of all the services recommended for these Chicago children, immunizations were the most conveniently obtained by families of low income. It is therefore of particular interest that among the families represented in this investigation failure to report for this type of service was no less frequent than for other types of care.

SIZE OF THE FAMILY GROUP AS A FACTOR IN THE HEALTH SERVICES OBTAINED

The number of children examined per family included in this follow-up study ranged from 1 child to 9 children. Among the 328 families represented there were only 29 children who did not require some type of professional attention. The average number in need of care among the white families was 2.5 children and among the Negroes was 2.3.

It has been noted that each child usually required care for several different conditions. In many instances the plan arranged to obtain the recommended services necessitated visits to a number of health facilities. More than a third of the families were referred to at least

Of the services advised, medical care was the most frequently needed and the least often secured by these families. Some type of medical service was recommended for 1 or more children in 9 of 10 of the families in the study. The majority of them took some steps toward carrying out the physician's recommendations, and 54 per cent of the families completed the services for at least 1 child in the family. An additional 12 per cent of the families obtained care for some of the health needs of all their children. However, 1 of every 5 families whose children required medical care made no attempt during the two and a half years of the follow-up to secure it. A graphic presentation of these data is given in the accompanying illustration.

Whether or not the recommended services were obtained appeared to be somewhat influenced by the size of the family group requiring attention. The average number of children in need of care among the families that completed the services was 1.8 per family, among those obtaining some service, 2.6 and among those failing to secure any professional care, 2.8. The figures on extent of care obtained by families with 1, 2

three different places—a few to as many as five centers—which often were a considerable distance apart. It is obvious that the problem of securing attention for all the health needs of the family group was not a simple matter for some of the families. Under these conditions, it is particularly interesting to find that 67 per cent of them obtained some service for every child in the family group that needed attention. Only 7 per cent of the families failed to report at least once to either a clinic or a private physician or dentist for some part of the services advised.

The extent to which recommended services were completed for all children in a family is indicated in table 4. Comparisons as to race and size of family are shown. The size is given in terms of one-child versus larger family groups, since the trend of the results in families of 2 or more children was similar. The table presents the over-all picture as to total professional services and as to those requiring medical services.

Approximately 1 in 4 families carried out all the recommendations made by the physician, and a like proportion completed the services for 1 or more children but not for the entire group. In other words, in half of the families some child received all the professional care advised for him. This was usually the child who had the fewest health problems.

and 3 or more children were: completed services, 47, 29 and 10 per cent; some service, 45, 65 and 78 per cent; no health service, 8, 6 and 12 per cent, respectively. It is evident from these comparative observations that the large family groups were as likely to obtain some care for their children as were the small families, although they were less likely to secure all the advised services. Among both the white and Negro families the size of the family group appeared to influence the amount of care obtained for the children.

With respect to medical care, all recommendations were carried out, as here interpreted, by 60 per cent of the one-child families and by 27 per cent of the larger family groups. In more than half of these larger families some of the children received all the service advised, and in still others some medical attention was obtained for all the children in need of it, although care was not completed for any of them.

These results clearly indicate that an attempt on the part of most of the families in this study was made to secure remedial and preventive care for their children, regardless of the size of the family group and other difficulties encountered in obtaining the required service. The effort put forth by these families that failed to carry out the recommendations is suggested by the figures in table 5.

REASONS FOR UNMET HEALTH NEEDS

In spite of some effort on the part of most families represented in this investigation, approximately half of the children who should have had medical attention failed to receive it. One or more children from 53 per cent of the families secured none of the medical

Extent of recommended medical services secured by 321 families for their children.

service advised for him. Why were the physician's recommendations not carried out? It was certainly not because these parents were uninterested in the welfare of their children. All of them had demonstrated their concern for the health of their children by accepting the opportunity to have them examined by a physician and by bringing them for the physical check-up—sometimes from a considerable distance. It was not because they did not know how to go about securing the recommended services, since all of them who did have a family physician were given assistance. Case workers aided them to locate the proper facilities where care could be obtained and also informed them as to the arrangements necessary to secure the required services. Why then did so many of these families fail to obtain the care advised for their children?

The explanations given by the families may not, and probably do not, reveal the real reasons for the unmet health needs of this group of Chicago children. However, their verbal reports should reflect significant attitudes on the part of these parents toward the health problems of their children and should serve to indicate some practical difficulties in the existing system of clinic services, particularly as it affects large families with small children.

The reason most frequently expressed by the families for their failure to return for care, and also for their failure to report at all, was that the children seemed well. They believed that the recommended health services were really not necessary because the children had no special complaints. In some of these cases, the mother indicated that the symptoms for which medical attention had been advised were still present but did not bother the child, or she thought that he would outgrow them as his older brother had. Most of these families had reported for some care, a number of them several times before discontinuing the services. By their own statements, however, they were not particularly impressed with the importance of remedial and preventive services for well children.

Various types of conditions relating to the general character of the services obtained and to the difficulties encountered in making use of facilities were complained of by these families. In some instances they refused to return to the clinics to which they were referred. In others they agreed to return but failed to do so, although they continued throughout the period of follow-up to express their intention to complete the services recommended. They objected to the duplication of the health check-up with no additional service provided at the time of the first clinic visit. It seemed to numbers of them that the clinic failed to realize the difficulty that the mother faced in keeping the various appointments for individual children made for different times instead of for the family as a group. Many complained of the numerous visits to different specialized clinics before the advised care for even one child could be carried out. They referred to the great distances they had to travel, the problem of taking a number of children to and from clinics, the long waits at the clinics and the children's unwillingness to continue under clinic care.

Unquestionably the long distances which some families had to travel to the clinics made the process of carrying out the recommendations a difficult one. The situation was further complicated for many of them by the fact that visits had to be made to more than one clinic. Merely to get the children to the different places where the recommended services could be started often entailed much effort and time. Although distance from the facilities was a seriously complicating factor in many instances, in none of the families did it appear to be the major factor involved in the extent to which recommendations for medical care were carried out. A map distribution of the addresses of the families and of the clinics to which they were referred showed that some of the families having the greatest distances to travel secured all the services advised for their children, while some families living within a few blocks of the clinics never reported at all.

During the years covered by this follow-up investigation there was a shortage of physicians and nurses, and long waits in physicians' offices and in outpatient departments of hospitals were of common occurrence in large cities all over the country. Since few of the clinics in Chicago operate on an appointment system—

* Summarized in tables 2 to 4 as receiving care.

other than specified days for special services or when certain physicians are available—the waiting periods for many of these families were frequently exceedingly long. In addition to the time involved there was the restlessness and discomfort of the children, as the rooms in which they waited were often overcrowded, with hard benches the only seating arrangement. Then, too, after the family had received some medical attention, if hospitalization or surgical treatment was required immediate care was usually not possible. The case would be placed on a waiting list. These conditions

tended to discourage even the most cooperative parents. For those who were not thoroughly convinced of the need for medical service, they were not infrequently sufficient reason for doing nothing about the recommendations.

The fears of the children and their unwillingness to continue under clinic care, with the consequent problem of forcing them to go, were mentioned as real difficulties in getting the required care completed. At the time of their health check-up the ages of the children ranged from 2 years to the early teens, the majority being between 6 and 12 years of age. This would mean that in the final year of the follow-up many of the children were old enough to go to the clinics alone. The records show that in a number of instances this did occur. It is not unlikely that the completeness of the health services in some family groups is directly related to the ages of the children needing care. In these cases, boys and girls sufficiently interested in their health condition might report regularly for the care advised and others in the family might never be taken to a clinic. Again, the older children might refuse to continue the services and the younger ones receive all needed attention. The age factor appeared to operate in both directions, as far as could be judged from the records. It was definitely associated with the completeness of dental care and immunization, perhaps largely because of the availability of facilities for these services in the schools and their accessibility to school children.

Less frequent explanations concerned family situations and behavior problems of the children, which at the time overshadowed the health needs; physical disabilities of the parent, which made trips to clinics difficult; home management problems (such as large households, invalids in the home to care for and no one to leave in charge of the household), and rejection of any type of medical service.

A few of the families refused to permit the remedial measures recommended. Surgical intervention was the service usually opposed by these families. In a small number of cases the records indicate the lack of interest of the mother and her unwillingness to cooperate with the worker and the clinic.

Arrangements to secure the needed services were worked out between the case workers and the families. There is some evidence, however, that the plan suggested by the case worker was not always satisfactory or entirely acceptable to the family. In some instances the facilities suggested were the only ones available to these families for the services required; in others they were mentioned because some member of the family had previously been treated at these clinics. In a relatively large number of the cases it was apparent from the records that the worker had either not given sufficient thought to the type of community resources which would best serve the needs of a particular family or that the framework within which this public agency operated did not permit a satisfactory plan. Many of the clinics to which families were referred offer comprehensive services, but a number of them restrict their services to specific conditions. When referrals were to the latter type of clinics the families usually were forced to go to several places if all the child's health needs were to be met.

The major responsibilities of the case workers in this follow-up investigation were concerned with providing opportunities whereby the families might secure the health services the children needed and reminding

them from time to time of the importance of having all defects corrected. Over the two and a half years covered by this study the main problem appeared to be that of getting the family to complete the services they had started. Approximately 3 of every 4 families that went to clinics failed to continue under care as instructed by the clinics. The fact that a number of the parents stated that they did not return to the clinics because they considered further care unnecessary clearly indicates their lack of understanding of the significance of the recommendations and of the plan of treatment. Some of the clinics to which these families failed to return have social service departments. But whether the interpretation of the care advised was the responsibility of the physician, the nurse or the medical-social workers or was shared jointly by a team of clinic workers, many of these families apparently remained unconvinced of the importance of continuing the clinic services.

From information obtained from the mothers it would thus appear that the reasons for the unmet health needs of this group of Chicago children are to be found in the cumulative effects of a series of difficult situations, together with little real appreciation on the part of the family of the value of early remedial care. Many of the difficulties encountered by these families of low income in their efforts to obtain medical and dental services are the result of conditions beyond their control.

CONCLUSIONS

The evidence from this follow-up of health examinations strikingly suggests that whether recommendations by the physician are carried out or not will be largely determined by two conditions. If parents thoroughly understand the significance of early remedial care to their children's general health and development and if the process of securing the required professional services is not too difficult, the care advised for the children will usually be obtained. The results of this study would seem to point to the importance of health education and particularly of adequate interpretation at the time a physical examination is made and continuously over the period of treatment, so that the relationship of remedial care to good health may be more generally understood. The difficulties in securing remedial care as disclosed in this investigation would also point to the need of providing facilities and procedures which would make medical and dental services accessible to those who need them.

Many communities provide for periodic examinations of children throughout their school years. Illinois now has a law which directs local authorities to provide regular health examinations for all public school pupils. Although some children will certainly benefit from these periodic contacts with the physician, unless remediable conditions discovered at these check-ups are corrected the time and effort expended on these programs will be in the main wasted. Furthermore, repeated diagnostic examinations without a follow-up of care are psychologically unsound, in that they tend to encourage a false sense of security with regard to the community's care for its children; in the minds of the children they will tend to minimize the values of good medical care.

If the children of this country are to be given the opportunity to grow into healthy adulthood, adequate facilities should be available so that corrections may be readily made when defects are discovered. The members of the medical profession share in the responsibility for achieving these ends.

Special Article**CANCER OF THE LIVER, BILE DUCTS
AND PANCREAS**ALEXANDER BRUNSCHWIG, M.D.
New York

This article is the fourth of a series to be published by the American Medical Association in cooperation with the American Cancer Society. The series is designed to aid in the early diagnosis of cancer and thereby to gain more effective results in treatment. When complete, the series will be published in book form by the W. B. Saunders Company under the sponsorship of the American Medical Association and the American Cancer Society.

Primary malignant neoplasms of the liver are not particularly common; they constitute about 0.2 per cent of all necropsies and about 2 per cent of all cancers. Males are more frequently affected than females, and although the highest incidence of these cancers has been observed in the fifth and sixth decades, they are not relatively infrequent in children and young adults.

Primary malignant hepatomas may be single or multiple, presenting rounded masses or nodules. It is extremely difficult to determine whether or not in a given case one focus is the primary growth and the others are metastases or whether there are multicentric foci of origin. Histologically, there may be primary liver cell carcinomas, or carcinomas arising from the biliary ducts. Sarcomas arising from the connective tissue elements may also occur but are much less frequent than carcinomas.

The presence of cirrhosis and carcinoma is not infrequently encountered, and this has given rise to the hypothesis that cirrhosis under certain conditions may be a precancerous condition, but there is little unequivocal evidence to support this view.

Symptomatology.—Patients with primary malignant neoplasms of the liver usually exhibit a rather rapid deterioration in their general nutritional state with appreciable loss in strength and appetite; secondary anemia of a severe degree is usually observed. A sense of growing discomfort and finally of pain in the upper part of the abdomen, usually on the right side, develops. There is progressive dyspepsia, and constipation may be a prominent complaint. Icterus develops relatively late.

On physical examination the liver may be diffusely enlarged and firm but not extremely tender. The surfaces may exhibit a nodulosity in cases in which multiple tumors are present. As stated, icterus is usually not present in the earlier stages of the disease and the spleen is not often enlarged. Roentgenographic examination reveals an increase in the size of the liver shadow, and the stomach and transverse colon may be displaced by the enlarged liver. Liver function tests are not especially helpful in diagnosis because of the large factor of safety of this organ.

As the disease progresses (fig. 1) icterus may develop, and the patient becomes increasingly conscious of the enlarging liver, the aggravation of pain and the loss of strength. Ascites eventually occurs in most

cases. Bouts of fever are common in these patients, especially in the advanced stages and as an accompaniment of icterus.

In the differential diagnosis it may be impossible to distinguish primary from secondary carcinoma of the liver in the absence of a demonstrable primary growth in other intra-abdominal viscerae. The observation of palpable tumor masses associated with the liver in the absence of general signs and symptoms of deterioration suggests benign neoplasm. Occasionally a large gumma of the liver may be mistaken, clinically, for neoplasm. In the presence of positive Wassermann or Kahn reactions a therapeutic trial with antisyphilitic drugs is indicated.

Frequently the question of whether the growth is primary or secondary can be settled by aspiration biopsy of the liver.

The prognosis in untreated patients is unusually grave, and death occurs within a few months once the symptoms are well developed.

Treatment.—Because the diagnosis is seldom made early or the process is diffuse, excision of the growth is in most instances out of the question. However, this does not mean that it should never be considered; quite the contrary. Exploratory laparotomy is indicated when the patient's condition is not too precarious. It is surgically feasible to resect large portions of the right lobe of the liver bearing a tumor; the entire left lobe can be removed. Resection is particularly facile if the tumor is situated near the edge of the organ and protrudes forward or downward with a pedicle of relatively small size (fig. 2).

A review of the literature¹ reveals that successful resection of primary malignant hepatomas has been recorded sufficiently often to warrant untenable a completely defeatist attitude in this respect. Some patients have survived for years.

Radiation therapy offers little beyond possible brief periods of palliation in cases in which the tumor happens to be radiosensitive.

In Hodgkin's disease and lymphoblastoma the liver may be involved. The spleen also is usually enlarged. Irradiation of the liver and spleen might afford brief periods of regression and amelioration of symptoms, but little in the way of prolonged arrest of the disease is to be anticipated when it is at the stage of hepatic involvement.

Fig. 1.—Photograph of girl aged 17 showing advanced stage of carcinoma of the liver (malignant hepatoma). L, enlarged liver filling the upper part of the abdomen; S, spleen enlarged secondarily. There is pronounced edema of the inferior extremities. The symptoms had begun seven months previously; general deterioration was extremely rapid. Death occurred two weeks after the photograph was taken. There were no metastases in the lungs.

SECONDARY MALIGNANT TUMORS OF THE LIVER

The liver, more than any other organ, is subject to secondary invasion by malignant neoplasm arising elsewhere, especially in the abdomen. In most instances of enlarged nodular liver due to secondary involvement the site of the primary growth elsewhere is obvious on

Fig. 2.—Various methods of excising hepatic neoplasms. *A*, relatively narrow pedicle of attachment is constricted by rubber tube prior to transection. *B*, V shaped excision; *C*, and *D*, repair of same; *E*, excision of entire left lobe of liver. Manual compression affords hemostasis until ligatures and sutures can be inserted; *F*, large continuous mattress sutures for compression to arrest hemorrhage. Gelatin or fibrin foam sponges may also be applied to raw surfaces for hemostasis (courtesy University of Chicago Press).

clinical examination. Often there is little clinical evidence to suggest secondary involvement of the liver, but this becomes apparent on exploratory laparotomy. When the liver is diffusely invaded by secondary growths, there is no therapeutic problem because nothing can be done. Radiation therapy is scarcely indicated in view of extensive trial in the past with generally poor results.

In recent years, with the improvements in general supportive treatment for the surgical patient and the extension of surgical practice in the treatment of cancer, the problem arises as to the advisability of resection of the primary growth in the abdomen together with the area of hepatic involvement when this appears to be sharply limited.²

The liver may be involved secondarily by intra-abdominal cancer in one of two ways: (1) by direct extension or (2) by discrete metastases. In direct extension of carcinoma of the stomach or transverse colon the neoplasm is adherent to Glisson's capsule. The latter is an effective barrier to the infiltration of malignant cells, and in most instances actual invasion of the growth through this capsule into the liver parenchyma has not occurred. When such adhesions to the liver have taken place, resection en masse of the primary growth and the hepatic extension should be carried out. The operative procedure is not difficult and offers the opportunity of prolonged survival, as illustrated in 2 patients living and well for more than five years.

In the case of multiple discrete hepatic metastases surgical excision is, of course, out of the question. However, in the presence of one or two discrete hepatic metastases I am of the opinion that excision of the primary growth and the metastases is indicated (fig. 3). It is realized that this view is at variance with the classic teaching of what constitutes an operable neoplasm; but when the abdomen is entered, if a resectable growth is discovered and one or two discrete metastases are also present, excision of the latter does not constitute an appreciable added strain on the patient and does afford the maximal of surgical effort, namely removal of all macroscopically evident neoplastic tissue. Whether or not this can be justified on the basis of increasing survival time in comfort is a question that would be extremely difficult to answer without extensive experience, which has not yet been obtained. But at least the surgeon would exert his maximal effort with little added disturbance to the patient. Evidence in favor of this view is the situation afforded by some patients in whom a solitary hepatic metastasis is observed but in whom only excision of the primary growth is carried out for palliation and who survive for periods of unanticipated length. Then there are those in whom nothing is done and who present at necropsy only one or few metastases. In these patients it is difficult not to consider that survival might have been prolonged had the metastases and primary tumor been excised. The presence of one hepatic metastasis usually indicates that others are present and may not

Fig. 3.—Photograph of surgical specimen consisting of right half of ascending colon with (*C*) carcinoma of cecum and large (*M*) bisected solitary hepatic metastasis removed at the same time from the dome of the right lobe of the liver. The convalescence was uneventful, and the patient has been free from symptoms nine months after operation and has returned to regular occupation, having gained 30 pounds (13.6 Kg.) in weight.

be detected or may still be of microscopic size; hence it might be argued that the removal of the one apparent metastasis could hardly alter the ultimate outcome. Although the strength of this argument cannot be denied, the fact remains that for some unknown reason

2. Brunswig, A., and Morton, D.: Resection of Abdominal Carcinomas Involving the Liver and Spleen Secondarily, *Ann. Surg.* 124: 746, 1946.

in some patients hepatic metastases may be solitary or few, and that therefore in order to afford these persons the benefit of surgical therapy solitary metastases should be excised when encountered, together with removal of the primary growth (provided, of course, that all macroscopic evidence of tumor is thus removed).

It is not particularly unusual at exploratory laparotomy to observe a resectable tumor and one or two small nodules in the liver. The first impression is that these are metastases and that the primary growth need not be excised or need only be short-circuited. Often such small nodules are fibrous or scirrhus angiomas or simple cysts. If the decision to remove a growth rests entirely on the nature of such hepatic observations, biopsy or excision of one of them for quick section should be carried out.

When a primary lesion in an abdominal organ is the cause of severe symptoms and is resectable, the presence of hepatic metastases should not invariably be the cause for failure to remove the growth, provided that the latter procedure is not exceedingly difficult. Appreciable palliation is often observed after the resection of such primary growths.

CANCER OF THE BILE DUCTS (AND GALLBLADDER)

Malignant neoplasms of the intrahepatic bile ducts present clinical problems inseparable from hepatic neoplasms, and these have been dealt with in the previous

TABLE 1.—Duration of Symptoms Before Operative Intervention

Patient No.	Age	Icterus	Abdominal Pain	Dyspepsia	Loss in Weight
.....	67	2 wks.	0	0	0
.....	63	3 wks.	? 3 wks.	3 wks.	0
.....	59	6 mo.	0	9 mo.	40 lb. in 9 mo.
.....	56	6 mo.	6 mo.	6 mo.	70 lb. in 8 mo.
.....	60	7 wks.	1 yr.	?	30 lb. in 3 mo.

.....	49	6 mo.	0	0	40 lb. in 6 mo.

sections. Those arising in the lowest segment of the common bile duct present problems identical with malignant tumors of the ampulla and head of the pancreas and will be dealt with in the next section. Carcinoma of the gallbladder and extrahepatic bile ducts constitutes about 4.5 per cent of all carcinomas apparent at necropsy and reported in the earlier literature; the incidence is probably less in recent years because of the extent in which cholecystectomy for cholelithiasis is now performed (W. H. Cole³).

Carcinomas of the extrahepatic biliary passages arise more frequently in the gallbladder than in the hepatic or upper common bile ducts. Invasion from one of these sites to the other apparently occurs rather rapidly via the rich lymphatic network present in these structures. Direct spread into the liver occurs more readily in cases in which the gallbladder is primarily involved, and diffuse hepatic metastases may occur relatively early, although this is by no means invariable, as some of the neoplasms apparently grow slowly. The process may be diffuse in the biliary tract walls or may be present as a circumscribed growth. In some instances the tumors are papillomatous.

Histologically the neoplasms are most frequently adenocarcinomas, but scirrhus carcinomas also occur. Indeed the latter, being composed of short strands or

cords of cells infiltrating a dense proliferation of fibrous tissue, are sometimes not readily detected, the whole process being regarded at first glance as inflammatory. In relatively infrequent instances the neoplasm will be of the squamous cell type.

Carcinoma of the extrahepatic biliary tract is a disease of late middle or advanced age.⁴ Much speculation has arisen in connection with the possible etiologic role of gallstones. In small laboratory animals the implantation of gallstones has been followed eventually in some instances by the development of carcinoma. Rolleston and McNee have pointed out that 4 to 14 per cent of all cases of cholelithiasis are associated with carcinoma. Evarts Graham and associates at the Barnes Hospital in St. Louis observed that 8.5 per cent of all proved cases of cholelithiasis were associated with carcinoma of the biliary tract. Fawcett and Rippman found carcinoma of the gallbladder in 12.3 per cent of 592 cases of gallstones encountered at necropsy.³ These observations lend some support to the view that temporizing with patients in early middle age who have symptoms due to cholelithiasis entails a failure to afford preventive measures in regard to cancer of the biliary tract (by cholecystectomy). I observed a patient aged 61 who had had one severe attack of biliary colic. Because of his age and the fact that he had experienced only one severe attack, he was not operated on. A year later he was brought back to the hospital with severe icterus and operated on as an emergency treatment. Cholecystectomy and choledochostomy were performed, but he succumbed on the fourth day (hepatorenal syndrome). Study of the specimen revealed in addition to acute cholecystitis and cholelithiasis a carcinoma in the fundus of the gallbladder about 2 cm. in diameter. Necropsy revealed no metastases.

Symptomatology.—The onset of symptoms is usually insidious. In a study of this question I found that in 7 patients with extrahepatic carcinoma of the biliary tract the most constant and striking sign was loss in weight accompanied by loss of appetite. Dyspeptic symptoms are at first vague and pain in the upper part of the abdomen is not a striking feature in the earlier stages. Icterus in most instances is a late sign, since at exploratory operation the disease of the icteric patient was invariably in the far advanced stages. Exceptions to this rule are those instances in which the growths are papillary and produce some degree of obstruction or in which they develop as circumscribed stenotic lesions in some portion of the hepatic or common ducts. The signs and symptoms as they were noted in the 7 patients with advanced carcinoma of the extrahepatic bile tract are given in table 1. Attention is called to the first 2 patients, who were practically asymptomatic until just prior to operative intervention, at which time the disease was found in an advanced stage.

Treatment.—Since the great majority of patients with carcinoma of the extrahepatic biliary tract undergo laparotomy late in the course of the disease, there is usually little that can be done. If the entire extrahepatic biliary tract is involved, this can be excised in attempted palliation. In a series of 7 such cases this operation was carried out, choleangiocholecystocholedochectomy, with appreciable palliation in 1 case; the patient, a man aged 68, was relieved of symptoms and returned to normal

3. Cole, W. H., in Christopher, F.: *Textbook of Surgery*, ed. 4, Philadelphia, W. B. Saunders Company, 1945.

4. Stewart, H. L.; Lieber, M., and Morgan, D. R.: Carcinoma of the Extrahepatic Bile Ducts, *Arch. Surg.* 41:662 (Sept.) 1940.

activity for a year. Briefer periods of palliation obtained in some of the other patients.⁵

In cases in which obstructive symptoms are produced by localized growths segmental resection of the involved structure with end to end anastomosis over a T tube or with choledochoduodenostomy has afforded in some instances prolonged survival even to several years.

Irradiation has little to offer in the treatment of these neoplasms.

Prognosis.—In cancer of the bile ducts (and gallbladder) the prognosis is almost uniformly bad, and the survival time varies from four to eight months after symptoms have become well established.

MALIGNANT TUMORS OF THE PANCREAS AND PAPILLA OF VATER

Carcinoma of the papilla of Vater arises from the duodenal mucosa over the surface of this structure, from the duodenal mucosa in its immediate vicinity or from the lining of the ampulla of Vater.⁶ The growths may be papillomatous or may produce ulcerations with raised borders. Nothing is known concerning the cause. The condition is observed in middle and advanced age with preponderance in the male sex; a few instances in young persons have been observed.

Symptomatology.—The onset of symptoms is usually exceedingly insidious, and the first symptom or sign may vary in different patients. There may be vague dyspeptic symptoms; there may be some epigastric discomfort; there may be an apparent unaccountable loss in weight and feeling of loss of strength; any or all these complaints may be present, to be followed by icterus which is at first mild and variable in severity but later becomes continuous and progressive. By the time icterus is well defined there will have been an appreciable loss in weight. The appearance of painless jaundice does not obtain invariably in all patients as the first apparent disturbance. In some instances moderate to severe melena may be an early sign, and this may be unaccompanied by abdominal complaints or even icterus.

With icterus the stools become light (clay-colored stools) and there may be steatorrhea.

On physical examination in addition to icterus, which is often quite severe, and the usual signs of recent loss in weight, palpation of the abdomen may reveal a rounded distended and tense gallbladder. This observation in the presence of icterus is known as Courvoisier's sign. The other frequent possible cause of obstructive icterus is an impacted calculus in the lower common duct. Since calculus formation is often the result of cholecystitis, the walls of the gallbladder being inflamed and rigid do not permit of its distention by obstructed bile. Obviously, therefore, Courvoisier's sign cannot be infallible as a diagnostic indication for neoplastic obstruction of the lower common duct, since cholecystitis with lithiasis may be present at the same time as carcinoma of the papilla of Vater. Furthermore, the patient's abdomen may be too thick or the liver too large to permit of palpation of a distended gallbladder. When present, Courvoisier's sign is of considerable importance; when absent, the presence of carcinoma is not ruled out. Because of their relatively small size carcinomas of the papilla of Vater are seldom palpable.

Laboratory studies usually reveal a secondary anemia. The degree and quality of icterus is determined by the icteric index and/or Vandenberg reactions. Blood amylase and lipase studies afford little unequivocal evidence for diagnostic purposes.

Repeated examination of the stools for occult blood when the patient is on a meat-free diet are of significance, because in the presence of obstructive icterus constant occult blood in the stools strongly suggests carcinoma of the papillary region of the duodenum, the latter being the source of the bleeding. I have observed near fatal hemorrhage from small (1 to 2 cm.) ampullar carcinomas.

Roentgenographic studies of the duodenum may be entirely negative due to the small size of the lesion and the difficulties of examining this portion of the alimentary tract. On the other hand, larger growths can be visualized as papillomatous or ulcerating lesions (fig. 4). The so-called reversed 3 (8) sign of Forstberg, indicates pronounced tense edema of the papilla of Vater which usually, but not always, is due to carcinoma.

Fig. 4.—Roentgenogram of barium fluoroscopy showing S, stomach; D, first portion of duodenum, and T, large filling defect due to neoplasm (carcinoma of papillary region). The patient was alive and well more than eight years after transduodenal resection of the neoplasm with reimplantation of the common bile and pancreatic ducts (courtesy of Radiology).

The differentiation from carcinoma of the extrahepatic biliary ducts is difficult if not impossible. The differentiation from carcinoma of the head of the pancreas is primarily of academic interest, since the treatment is the same, as will be shown later.

Prognosis.—The rapidity of growth, spread and metastasis vary widely in different patients. An average duration of seven months has been reported by some authors after the development of icterus. However, in some patients in whom short circuiting operations have been performed to relieve icterus, there has been survival for two to five years or more. Prior to the advent of vitamin K, death not infrequently occurred from cholemic hemorrhage and necropsy revealed that the growth was still localized to the papillary region.

PANCREAS

Malignant tumors of the pancreas are most frequently observed in patients of middle and advanced age. Nothing, of course, is known of their causation.

The most frequent type of malignant pancreatic neoplasm is duct cell carcinoma, of which there are several

5. Brunschwig, A., and Bigelow, R. R.: Advanced Carcinoma of the Extrahepatic Bile Ducts: Choleangiocholecystocholedochectomy, *Ann. Surg.* 122: 522, 1945.

6. Lieber, M.; Stewart, H., and Lund, H.: Carcinoma of the Papillary Portion of the Duodenum, *Ann. Surg.* 109: 219, 1939.

varieties, depending on the anaplasia of the cells and the manner in which tubular structures are formed. Usually there is sufficient proliferation of the fibrous tissue to afford a dense firm consistency to the mass, i. e., scirrhous carcinoma. Carcinomatous degeneration of acinar tissue forming true medullary carcinoma is indeed rare if it ever occurs at all. Also infrequent is squamous cell metaplasia in some portions of a typical duct cell carcinoma. Fibrosarcoma and lymphosarcoma primary in the pancreas are also rare.

Cystadenomas of the pancreas are multilocular tumors, usually quite bulky when discovered at operation. The locules contain serous or viscous fluid that is colorless or dark brown, clear or cloudy. These tumors are for the most part benign but in some instances exhibit local spread beyond the pancreas and metastasize.⁷

Pancreatic cysts are benign lesions but on rare occasions are associated with carcinoma.⁸ Such instances probably represent pancreatic cyst formation concomitant with carcinoma or secondary to disturbances in the pancreas due to the extension of the carcinoma rather than malignant degeneration of a preexisting true cyst.

Symptomatology.—The symptomatologic manifestation of pancreatic cancer may be considered in two parts; i. e., that associated with cancer of the head of

Laboratory studies are not particularly characteristic; they reveal secondary anemia and an obstructive type of icterus, usually severe. The stools are acholic in proportion to the severity of the icterus. Aspiration of duodenal contents for study of the ferments present in order to secure evidence of occlusion of pancreatic juice are not generally carried out.

Prognosis.—In untreated patients the natural course of the disease lasts several months before death ensues from pneumonia, cholemic hemorrhage or general exhaustion (cholemia).

CARCINOMA OF THE BODY OF THE PANCREAS

Carcinoma of the body of the pancreas is less frequent than carcinoma in the head of the pancreas. Statistical studies show that 10 to 25 per cent of carcinomas of this organ arise in the body or tail. Males are three to four times more frequently affected than females, the age incidence being highest in the fifth and sixth decades of life.

Symptomatology.—Because the body and tail of the pancreas are anatomically somewhat removed from the alimentary or biliary tracts, obstructive symptoms of one or the other type do not occur, at least until the final stages of the disease.

The early symptoms are vague indeed and usually are those of dyspepsia, especially eructations, loss of appetite and constipation; there is progressive weakness and loss of weight and strength. Pain is the outstanding and characteristic symptom. This is present in the epigastrium, especially in the left upper quadrant, and has a decidedly characteristic pattern of radiation, namely to the hypochondriac regions and through to the back. A complete high girdle distribution is also common and characteristic. The pain of the patient is more or less constant; it is often aggravated by lying down and relieved partially by the sitting position.

Physical examination usually reveals a state of nutritional deterioration. On palpation of the abdomen there may be tenderness over the region of the body of the pancreas. A deep seated resistance may be elicited, or a definite deeply situated mass with indefinite outlines may be palpable. Icterus may occur late in the course of the disease and is due to extension of the growth from the body of the gland into the head.

Röntgenographic studies are usually negative, but some workers by persistent interest in the problem have reported successful demonstrations of bulging of the tumor mass into the stomach. Likewise gastroscopic examination, usually negative, has on some occasions revealed mucosal changes due to secondary involvement of the stomach by the primary growth in the pancreas.

Laboratory studies do not afford information of special significance, other than the observation expected in a patient who presents considerable nutritional deterioration.

TREATMENT OF CANCER OF THE PANCREAS

A discussion of the treatment of pancreatic cancer will be prefaced by certain remarks to the general practitioner who, because of the vagueness of the symptoms and signs, is so often consulted by patients in the early stages of this condition.

It is imperative that these tumors be diagnosed in the early stages because, unlike the situation fifteen years or more in the past, surgical attack on them has

TABLE 2.—Some Collected Results of Pancreatoduodenectomy for Carcinoma of the Pancreas or Ampulla of Vater

Author	Number of Cases	Postoperative Mortality
Whipple, A. O.: collected series to April 1942	Two stage 41 One stage 23	12 (29%) 8 (35%)
Orr, T. G.: collected series, April 1942 to November 1944	Two stage 15 One stage 19	4 (26%) 6 (32%)

the pancreas and that associated with cancer of the body and tail.

In the head of the pancreas the onset may be insidious with the development of painless jaundice. On the other hand, the development of icterus may often be preceded by dyspeptic symptoms which may become quite pronounced. Epigastric pain is frequently present and is generally localized to the region of the head of the pancreas with radiation through to the back. This pain is often constant and sometimes aggravated by the patient's lying down and relieved by his sitting up. Nausea is a frequent complaint. There is loss of weight and strength. Constipation is a frequent complaint and often becomes extremely pronounced.

On physical examination icterus is the most apparent sign, together with the general observation of pronounced loss in weight. Palpation of the abdomen may reveal a distended gallbladder (Courvoisier's sign, discussed previously). Not infrequently a mass is palpated in the region of the head of the pancreas. This is deeply situated and possibly tender; its outlines are indefinite, and it does not descend with inspiration. Failure to palpate a mass does not rule out the presence of carcinoma of the head of the pancreas, nor do negative roentgenographic studies. Positive roentgen observations include a widened duodenal curvature, evidence of rigidity of the inferior wall of the pylorus or actual lesions involving the concave border of the duodenum.

7. Kennard, H.: Papillary Cystadenocarcinomas of the Pancreas, *Surgery* 9: 65, 1941.

8. McWhorter, G. L.: Cysts of the Pancreas, *Arch. Surg.* 11: 619, 1925.

been made possible.⁹ To be sure, the results achieved to date are not extremely brilliant as far as numbers of patients salvaged for prolonged periods are concerned (table 2), but the majority of patients operated on have been in the advanced stages of the disease and prolonged survival was not to be anticipated. The same situation existed in regard to gastric cancer. It required several decades for gastrectomy to become established and carried out on a wide scale. Indeed, shortly after its introduction not a few of the outstanding figures in medicine of the day decried its performance as too radical and predicted a limited usefulness. The early results of excision of tumors of the central nervous system and lung taxed the perseverance of the pioneers in these fields, but finally the problems of technic, morbidity and mortality were surmounted. Therefore, while the situation not many years ago was that an early diagnosis afforded no practical advantages since nothing could be done about the situation anyway, today these neoplasms can be resected with return of the patient to normal life (figs. 5, 6 and 7).

Fig. 5.—Photograph of surgical specimen secured by one stage pancreatoduodenectomy showing S, lower part of the stomach; D, duodenum; P, head of pancreas; C, opened common bile duct, and T, small carcinoma in head of pancreas just beneath ampullary region. The patient is living and well over three and a half years after operative intervention.

Furthermore, because of the vagueness of the clinical picture which often obtains in the early stages of pancreatic cancer, persistence of these symptoms, failure to obtain relief by the usual therapeutic management and above all an unaccountable loss in weight indicate the advisability of exploratory laparotomy to rule out the presence of cancer. This problem, of course, requires the best of clinical judgment and acumen. When all the signs and symptoms of pancreatic cancer are present and there is little doubt as to the situation, the disease has usually progressed to an advanced stage in which little more than palliation is possible.

Operations for Resection of Carcinoma of the Papilla of Vater.—(a) In transduodenal resection (fig. 8) the duodenum is incised longitudinally on the anterior aspect of the lower portion of the second segment. The lesion involving the papilla is resected by elliptic incisions encompassing it and extending through the duodenal wall. The transected common bile and pancreatic ducts are sutured into the wound and the latter completely closed.

9. (a) Whipple, A. O.; Parsons, W., and Mullins, C.: Treatment of Carcinoma of Ampulla of Vater, *Ann. Surg.* 102:763, 1935. (b) Brunschwig, A.: *The Surgery of Pancreatic Tumors*, St. Louis, C. V. Mosby Company, 1942.

Transduodenal resection is carried out in well localized lesions, papillomatous in character, which are obviously superficial and confined to the duodenal mucosa or ampulla. Some patients have survived for

Fig. 6.—Surgical specimen secured by one stage pancreatoduodenectomy: Py, pylorus; Hd, head of pancreas; P1, metal probe in accessory pancreatic duct; P2, metal probes in main pancreatic and lower common bile ducts, respectively, protruding through Ca, large papillary carcinoma of papilla of Vater; Met., metastatic node removed from above the cystic duct. The operation was performed in May 1943.

Fig. 7.—Photograph of surgical specimen obtained by right hemicolectomy (C, carcinoma of ascending colon and M, mesenteric lymph node metastases) from same patient from whom specimen shown in fig. 11 was removed. The operation was performed in January 1946.

years after such types of excision in cases in which the histologic diagnosis was carcinoma. (b) Radical resection.

Operation for Resection of the Head of the Pancreas.—In pancreatoduodenectomy (radical excision of carcinoma of the papilla of Vater (fig. 9) the head of the pancreas and the duodenum are removed in toto. The peritoneum along the convex margin of duodenum is

fat is not sufficient to maintain adequate nutrition, pancreatin is given by mouth with meals. No other substitution therapy is apparently necessary.

In the presence of inoperable growths relief from icterus may be attempted by cholecystogastrostomy or cholecystojejunostomy.

Operation for Resection of Body and Tail of Pancreas¹⁰ (fig. 11).—The transverse mesocolon is divided with retraction upward of the stomach and downward of the transverse colon. This exposes the body and tail of the pancreas. The spleen is freed from gastric, colic and diaphragmatic attachments by the division of vessels and ligaments. It is then grasped by the right hand and elevated, the body and tail of the pancreas being brought upward with it. The pancreas may then be divided at a level of election to permit of excision of a tumor arising in it. The site of excision is drained and the transverse mesocolon reconstituted.

Total pancreatectomy has been performed successfully on a number of occasions.¹¹ Apparently insulin and a full diet are all that are necessary to maintain normal nutrition. The interesting result of metabolic studies in these patients is that the degree of diabetes is relatively mild,

the patients requiring only 20 to 30 units of insulin a day. In 1 patient who had severe diabetes and carcinoma of the body of the pancreas, total pancreatectomy was performed and the degree of diabetes was not enhanced following the operation. Indeed, it may have been decreased.¹²

Fig. 8.—Diagram of transduodenal resection of carcinoma of the papilla of Vater.

incised to permit elevation of the head of the pancreas and duodenum. The ligament of Treitz is transected. The lower portion of the stomach is transected and the upper segment closed. The neck of the pancreas is divided over the superior mesenteric vessels. The common duct is divided at the level of the superior border of the first segment of duodenum. The jejunum is transected a few centimeters distal to the ligament of Treitz. The lower part of the stomach, head of the pancreas and the duodenum are removed. A gastrojejunostomy is performed (Billroth II). The next long loop of jejunum is brought upward for choledochojejunostomy. An enteroenterostomy is done between afferent and efferent loops to the latter anastomosis. The neck of the pancreas is ligated by several interlocking mattress sutures; a separate ligature is placed about the transected duct of Wirsung. Drains are placed to the transected pancreas and to the previous site of duodenum and head of pancreas.

Other methods of reconstituting the upper portion of the alimentary tract have been described and successfully carried out (fig. 10). Among these is the reimplantation of the transected neck of pancreas into the jejunum in an attempt to return external pancreatic secretion to the bowel. However, patients may do comparatively well with occluded external pancreatic secretion. The stools may be practically normal; more often fat absorption is not normal and they are bulky, light in color and foul. When the absorption of

Fig. 9.—Diagram showing operation for radical excision of head of pancreas, lower part of stomach, entire duodenum, first few centimeters of jejunum for carcinoma of papilla of Vater and/or carcinoma of head of pancreas (Brunschwig's technic) (courtesy Surgery, Gynecology and Obstetrics).

INSULIN-PRODUCING ISLET CELL TUMOR OF THE PANCREAS

Most insulin-producing islet cell tumors of the pancreas are benign, but a number of malignant ones

10. Brunschwig, A.: The Surgical Treatment of Carcinoma of the Body of the Pancreas, *Ann. Surg.* 120: 406, 1944.

have been observed.¹³ I know of no instance of islet cell adenoma which at operation was excised and in which there were subsequent developments of metastases. Those that were malignant presented metastases at the time of operation.

The diagnosis is made by observing the following features (triad of A. O. Whipple): (1) Attacks of weakness, dizziness, flushing, amnesia or actual coma coming on after periods of starvation or of muscular exertion; (2) relief obtained by ingestion of food and/or injection of dextrose, and (3) blood sugar levels of 50 mg. or less per hundred cubic centimeter during the attack.¹⁴

The foregoing features are also characteristic of insulin-producing benign islet cell tumors and call for exploratory laparotomy. The solitary or multiple benign islet adenomas of the pancreas are excised locally. In the case of malignant tumors, the primary growth is excised and, if feasible, the metastases also.

Fig. 10.—Diagrams of procedures devised by (A) Whipple and by (B) Cattel for reimplantation of transected neck of pancreas into jejunum following pancreaticoduodenectomy. Cholecystojejunostomy is performed rather than cholecystojejunostomy.

Fig. 11.—Diagrammatic representation of method for resection of body and tail of pancreas for neoplasm (courtesy C. V. Mosby Company).

Hypoglycemia of the order of 60 to 70 mg. per hundred cubic centimeters of dextrose in the blood is probably not on the basis of insulin-producing islet cell tumor and can be managed by proper dietary regimens. In a few instances hypoglycemia of the order previously described for islet cell tumor led to exploratory operation with failure to discover a tumor. Radical pancreatectomy (body and tail resected) afforded relief

from an attack of hyperinsulinism. Persistence of such attacks after the removal of the body and tail of pancreas strongly suggests the presence of an undetected islet cell adenoma in the head of the pancreas.

Clinical Notes, Suggestions and New Instruments

TEST FOR LOCATING THE POSITION OF THE TIP OF THE MILLER-ABBOTT TUBE

SAMUEL McLANAHAN, M.D.
Baltimore

The principle of intestinal intubation by means of the double lumen suction tube or latterly by the newer single lumen mercury-weighted tubes is one of the great advances of modern therapeutics. Originally developed by Miller and Abbott¹ for investigative purposes, the clinical possibilities of the double lumen tube were soon appreciated and realized.² In intestinal obstruction, it has served as a primary therapeutic measure in selected cases and as an adjuvant measure to surgical treatment in many others. It plays an increasingly useful role when introduced preoperatively, when elective intestinal resection is anticipated.

Two problems are likely to be encountered during the introduction of the tube. The first problem relates to the difficulty of having the tube traverse the pylorus and enter the duodenum. It is a matter of common observation that the more urgent the need for the tube, the more difficult it is to accomplish this feat. A variety of tricks and maneuvers have been described to facilitate the passage of the tip and the balloon through the pylorus. Probably the most widely used of these is the introduction of metallic mercury into the balloon as described by Harris.³ This method is now employed routinely.

The second problem, and the one with which this report is primarily concerned, is the determination of whether the end of the tube has actually passed into the intestine, or whether, with its further introduction, the tube is merely becoming coiled up in the stomach. It is imperative that this fact be established, if one is desirous of having anything more than gastric suction. Furthermore, with the tube advancing as planned into the small intestine, it is well to know in what part of the abdomen the suction tip lies. This information may at times assist in the placing of an incision.

Several methods are available for determining the position of the indwelling tube. Fluoroscopic or roentgenographic examination can give more accurate information than any other available means. With some experience, one can tell whether the tip is in position to pass or has passed the pylorus. If it has passed, one estimates the amount of small intestine which has been intubated. Other methods depend on the character of the drainage being recovered, the time required for fluid taken by mouth to be aspirated, the demonstration of rhythmic peristalsis in a syringe attached to the balloon connection and the downward traction on the tube produced by peristaltic activity in the intestine.

The test about to be described is simple yet effective. It involves abdominal auscultation carried out simultaneously with the production of a noise within the balloon or at the suction openings in the tube. The only requirements are an observer and an assistant, a stethoscope and a syringe.

THE TEST

A Luer syringe of at least 20 cc. capacity is filled with 15 or 20 cc. of air and attached by the assistant to the tubing leading to the balloon of the Miller-Abbott tube. The assistant steadily

introduces and withdraws the plunger alternately so as to inflate and deflate the balloon. This serves to create within the abdomen a noise, actually a "racket" to the observer listening with his stethoscope. The amount of air introduced with each movement of the plunger and the speed of the movements are variable; the effort being made to produce a continuous sound for the observer. He moves his stethoscope about the abdomen, selecting the area or point of maximum intensity of the sound. If the tip has passed on into the intestine, experience shows he will find a definite point beneath which the sound of air rushing in and out of the balloon seems almost to be in his ears. If, on the other hand, the balloon remains in the stomach, the sound will not be as sharply localized, but will be audible across the epigastrium, especially to the left and in general over the area where the stomach is known to be situated. In addition, the sound takes on a somewhat resonant quality, dependent apparently on its presence in a larger viscus. Because of this diffuse character and resonant quality, one does not undertake to determine in what part of the stomach the tip lies.

Satisfactory sounds, though less clearly audible, can be produced by utilizing the suction tube itself instead of the balloon. This means that the test is also applicable to the newer single lumen tubes with mercury bulb attached designed by Harris⁴ and Cantor.⁵ Less accurate localization is possible because of the multiple openings in these tubes for suction; but one can in most instances readily and promptly confirm or disprove the impression that the tube has passed well into the intestine.

This test has been employed for more than two years on many patients, and the observations have been repeatedly checked by roentgen examinations and by other means. The speed and

involves the expense of the roentgenograms to the patient or the hospital, an expense which may be multiplied many times if repeated roentgenograms are required.

SUMMARY

A test is described for ascertaining the location of the advancing suction tip of the Miller-Abbott tube and especially for determining whether the tube has left the stomach and entered the intestine. The test depends on stethoscope auscultation of the abdomen by the observer, while an assistant alternately inflates and deflates the balloon with air. The observer determines the point of maximum intensity of the sound and this indicates the position of the tip. If the tube is still entirely within the stomach, the sounds take on certain special characteristics. The test is applicable, though with less accuracy, to the single lumen tubes, the air being passed in and out of the suction tube itself. The great advantage of this method lies in reducing the necessity for roentgenographic examination with its consequent expenditure of effort by all concerned, its consumption of time and its cost.

Council on Pharmacy and Chemistry

REPORT TO THE COUNCIL.

ORGANOMERCURIAL COMPOUNDS

The Council on Pharmacy and Chemistry presents the following report by Drs. Morton and North and Mr. Engley as a further challenge to the scope of usefulness of mercurial antiseptics. The potency of mercury, as either an inorganic or an organic compound, to inhibit growth in bacterial cultures is so striking that it created the presumption of high disinfectant potency. This presumption was severely shaken when it was proved that the inhibited bacteria are not killed by the mercurials but resume lusty growth when the adherent mercury is sufficiently diluted or when it is removed chemically by sulfur compounds. Nevertheless, the use of mercurial antiseptics has continued, especially in the form of organic compounds of low systemic or local toxicity. This could be defended in a degree on the basis that bacteriostasis would at least tend to decrease the number of bacteria and thus the chance of infection. Whether this actually applies to the special conditions of the clinical use of these mercurials should be the subject of carefully controlled experimentation and not of *a priori* arguments. So far the proof does not fully satisfy the standards of scientific criticism.

It could also be argued, or hoped, that the mercury inhibition of growth would impair the infectivity of the bacteria, perhaps irreversibly. This too should be the subject not of argumentation but of experimental verification. This is the chief purpose of the present report, and the answer under the conditions of the experiment reported is in the negative: Bacterial cultures which have been exposed for ten or even fifteen minutes to the full commercial concentration of three of the most widely used organic mercurial agents produce fatal bacteremia when injected intraperitoneally into mice. The tests were made with a non-spore-forming organism, a virulent hemolytic streptococcus "pathogenic for man and mouse," and the results are decisive. Whether other infectious agents would differ and lose their virulence when exposed to mercury may well be investigated. Actually, in other experiments in the same laboratory it has been found that the infection of laboratory animals by influenza virus may be prevented by their exposure to "mercurochrome," "merodicein," "metaphen" and phenyl mercuric nitrate; "merthiolate" was ineffective. Others have reported the effectiveness of "mercurochrome" in inactivating *in vitro* the virus of poliomyelitis. The field of usefulness of organic mercurials should be explored, proved and defined. The proponents of these preparations should proceed seriously and diligently to this task. The Council wishes to give the necessary opportunity to meet the challenge, but it should not be deferred indefinitely. It is a field in which wishful thinking is dangerous.

AUSTIN SMITH, M.D., Secretary.

B. eight independent observers have each recorded the point of maximum intensity of the sound as determined by stethoscope auscultation, according to the technic described.

accuracy of one's observations improve with practice. In occasional instances, the findings may be equivocal or unsatisfactory and the characteristic sounds are not heard. These instances are usually attributable to technical complications, such as kinking of the tube, so that the air does not readily pass, and rupture of the balloon, making it impossible to inflate and deflate it.

The figure illustrates a recent evaluation of this test whereby eight physicians, most of whom had never tried the test, were asked independently to observe and record the point of maximum intensity of the sound. The results are shown on the chart along with the roentgenogram of the same patient, taken a short time previously.

The great value of this test lies in its simplicity and applicability. Most observers must depend solely on abdominal roentgenograms to ascertain the position of the tube. Such an examination involves either moving the patient to the x-ray machine or the machine to the patient; it involves a lapse in time until the picture can be secured and viewed, and, finally, it

THE BACTERIOSTATIC AND BACTERICIDAL ACTIONS OF SOME MERCURIAL COMPOUNDS ON HEMOLYTIC STREPTOCOCCI

In Vivo and in Vitro Studies

HARRY E. MORTON, Sc.D.

LEON L. NORTH Jr., M.D.

and

FRANK D. ENGLELY Jr., M.S.
Philadelphia

Mercurial compounds have been employed as disinfectants since the beginning of bacteriology. Indeed, for a long period mercurial compounds, such as bichloride of mercury, headed the list of chemicals which were thought to be effective in the killing of micro-organisms. This perhaps may be attributed to the favorable publicity which Koch¹ in 1881 gave to bichloride of mercury during his work with the organism causing anthrax. In substance he stated that, without special preparation of the objects to be disinfected, bichloride kills by a single application of a very dilute solution, and in a few minutes even the most resistant forms of the organisms are killed.

Geppert² in 1889 first pointed out that false inferences were drawn that bacteria were killed by the action of bichloride of mercury when growth of the organisms was prevented by traces of the chemical in the culture medium. In support of his thesis Geppert claimed that the spores of *Bacillus anthracis* were capable of infecting animals even after the spores had been treated with bichloride of mercury and produced no growth on subculturing by the usual methods. To eliminate the bacteriostatic action of the small quantity of mercury adherent to the bacteria and of the small amount of the chemical carried into the subculturing medium in the inoculum, Geppert employed ammonium sulfide to inactivate the bichloride of mercury. By this technic Geppert showed that the spores of *B. anthracis* were not killed by 1:1,000 bichloride of mercury during a period of exposure of hours, in one case as long as twenty-four hours.

In 1891 Abbott³ claimed that he had confirmed Geppert's work in part, but he did not do animal experiments. In his publication in 1891, Abbott concluded, ". . . it is plain that for use in surgical practice the solutions of corrosive sublimate do not possess all of the advantages hitherto attributed to them."

Do other compounds of mercury possess the same shortcomings as disinfectants⁴ as does bichloride of mercury? Are non-spore forming pathogenic micro-organisms still infectious while in a state of bacteriostasis brought about by a mercurial compound? The answers to these important questions are provided by the experimental work to be described.

From the Department of Bacteriology, University of Pennsylvania School of Medicine.

These studies have been aided by a grant from the Council on Pharmacy and Chemistry, American Medical Association.

REASONS FOR AND MEANS OF PREVENTING THE BACTERIOSTATIC ACTION OF MERCURIAL COMPOUNDS IN GERMICIDAL TESTS

It is generally known that it is exceedingly difficult to destroy bacterial spores. Our results, about to be described, indicate that virulent hemolytic streptococci (an example of non-spore forming organisms) are still infectious after being exposed for ten minutes to any one of three organic mercurial compounds obtained in the open market. The compounds studied were (1) the disodium salt of 2,7-dibrom-4-hydroxymercurifluorescein, merbromin, N. F., "mercurochrome," (2) sodium ethylmercurithiosalicylate, "merthiolate," (3) the anhydride of 4-nitro-3 hydroxymercuri-orthocresol, "metaphen." The fact that both vegetative cells and spores are still infectious while in a state of bacteriostasis is sufficient reason for taking precautions to eliminate the bacteriostatic effect of mercury when testing mercurial compounds in vitro for germicidal activity. In the in vitro test, micro-organisms are mixed with the chemical under test and at stated intervals portions, usually a standard loopful, are transferred to an appropriate subculturing medium. It is quite generally accepted that germicides in solution bring about their action by reacting chemically with the bacterial cell. When a portion of the germicide-culture mixture is transferred into the subculturing medium, in order to determine whether the organisms are still viable some of the germicide is introduced into the subculturing medium, both free in the solution and in combination with the bacterial cells. In testing strong solutions of germicides it was realized that in some cases it was possible to carry enough of the chemical in an inoculum the size of a standard loopful into the subculturing medium to give a concentration of the germicide in the subculturing medium great enough to exert a bacteriostatic action. Shippen⁵ in 1928 recommended transferring four loopfuls from each subculture of the culture-germicide mixture to a second tube of broth. In this way the germicide would be diluted beyond the concentration at which it would be able to exert a bacteriostatic action. By this technic he found that bichloride of mercury in a dilution of 1:200 to 1:300 failed to kill *Staphylococcus aureus* in fifteen minutes' exposure. This concentration of bichloride of mercury is three to five times as great as usually recommended and is still incapable of destroying in fifteen minutes' exposure the vegetative cells of the common pus producing organism. Mere dilution of the inoculum does not eliminate the bacteriostatic action of the mercurial contained in it. Heinemann⁶ pointed out that dilution of the inoculum as in the Shippen technic gave falsely high killing values in several instances. This was also demonstrated by Morton⁷ with soaps containing mercurial compounds. It has been pointed out also that dilution does not neutralize the mercury which may be bound to the bacterial cell.

Bacterial cells which have been weakened by exposure to the action of a germicide are more susceptible to the bacteriostatic action of the germicide, so it is more difficult to eliminate the bacteriostatic action of the chemical. This was pointed out by Geppert² and was

emphasized in one of the early textbooks on bacteriology.⁸ For a fuller discussion of the shortcomings of mercurial compounds as disinfectants reference should be made to the report of Brewer⁹ in 1939.

A method more reliable than mere dilution for eliminating the bacteriostatic effect of a mercurial compound in the subculturing medium during the testing for germicidal action is chemical neutralization of the mercurial. Geppert employed ammonium sulfide to inactivate the mercury in the culture-germicide mixture which was subcultured and found that the dilutions of bichloride of mercury which were germicidal were much lower than when cultured by ordinary methods. Hunt¹⁰ employed hydrogen sulfide for the same purpose. The thioglycollate medium described by Brewer¹¹ in 1940 for growing micro-organisms anaerobically was also found to be capable of neutralizing the bacteriostatic action of mercurial compounds.¹² The National Institute of Health made this the official medium for the sterility testing of biological products beginning July 1942, and it has been subsequently modified to a slight extent (Pittman,¹³ N. I. H. circular.¹⁴)

The objectives of our experiments were to determine (1) the effect of some of the organic mercurial compounds on an organism pathogenic for man and mouse and (2) whether the growth of the test organism in thioglycollate medium parallels infectivity for the animal body.

MATERIALS AND TECHNIQUES

Test Organism.—It is desirable to select for test organisms those which are pathogenic for man as well as for some laboratory animal. We selected for this work *Streptococcus pyogenes*, strain C203M. It gave a good reaction with group A serum (Lancefield). On extract agar containing 5 to 10 per cent normal horse blood the streptococcus colonies were surrounded by large zones of hemolysis of the red blood cells. The red blood cells in blood broth were readily hemolyzed. The culture was maintained in blood extract broth composed of Bacto-beef extract 0.3 per cent, Parke-Davis peptone 1 per cent, sodium chloride 0.5 per cent and distilled water. The p_H was approximately 7.2 after sterilization. Sterile defibrinated horse blood was added to the amount of 10 per cent. Approximately 10 cc. of medium was contained in the culture tubes. Fresh subcultures were made by transferring 0.5 cc. of a previous culture to a tube of fresh medium, incubating at 37 C. for twenty-four hours, then storing in the refrigerator at 4-11 C. The stock cultures were routinely subcultured every three months. Three out of three mice were killed within sixty-five hours following the intraperitoneal injection of 1 cc. of a 1:10,000,000 (1×10^{-7}) dilution of a twenty-four hour culture. The lethal dose constituted four colonies when grown in blood extract agar.

Experimental Animal.—White Swiss mice weighing 17-20 Gm. each were employed.

Culture Mediums.—Bacto-Anaerobe medium with dextrose, experimental, contained in each liter Proteose-peptone No. 3, Difco, 20 Gm., Bacto-beef extract 3 Gm., Bacto-yeast extract 3 Gm., malt extract, Difco, 3 Gm., dextrose 5 Gm. and agar 1 Gm. Reaction of the medium after sterilization was approximately p_H 7.3.

Bacto-cooked meat medium No. 2 was a special lot for a contaminated wound project. Each liter of medium contained beef heart 454 Gm., proteose-peptone, Difco, 20 Gm., dextrose 2 Gm. and sodium chloride 5 Gm. Reaction of the medium after sterilization was approximately p_H 7.4.

Bacto-tryptose phosphate broth contained in each liter Bacto-tryptose 20 Gm., Bacto-dextrose 2 Gm., sodium chloride 5 Gm. and disodium phosphate 2.5 Gm. Reaction of the medium after sterilization was approximately p_H 7.3.

Hydrolyzed casein. This was received from Dr. C. M. Brewer, U. S. Department of Agriculture, who stated that it was "Trypticase-Pancreatic Digest of Casein" received from the Baltimore Biological Laboratory. A 3 per cent solution in distilled water containing 0.5 per cent sodium chloride was used. It had a reaction of p_H 6.8 after sterilization.

Bacto-fluid thioglycollate medium, Linden formula, was prepared in accordance with section 4 b of the National Institute of Health Bulletin "Fluid Thioglycollate Medium for the Sterility Test," dated Dec. 30, 1941. Each liter of the medium consisted of Proteose-peptone No. 4, Difco, 30 Gm., Bacto-dextrose 5 Gm., Bacto-yeast extract 2 Gm., sodium thioglycollate, Difco, 1 Gm., Bacto-agar 0.5 Gm., sodium chloride 5 Gm., dipotassium phosphate 2.5 Gm., Bacto-methylene blue (DA-6) 0.002 Gm. and distilled water. The reaction was approximately p_H 7.5 after autoclaving.

For a plating medium beef extract agar, made by adding 2 per cent agar to the beef extract broth, was used, to which was added 10 per cent sterile, defibrinated horse blood.

Disinfectants.—Samples of the three organic mercurial compounds "Mercurochrome," "Merthiolate" and "Metaphen" were purchased over the counter from various pharmacies and used undiluted from the original packages or diluted as for the standard phenol coefficient test.¹⁵

Technic.—In performing the disinfection tests, 1 cc. of a 24 hour old blood broth culture, $\pm$ 2 hours, was added to 10 cc. of the disinfectant in a test tube. After thorough mixing, 5 cc. of the culture-disinfectant mixture was transferred to an Esmarch dish to facilitate filling syringes. At intervals of five, ten and fifteen minutes 1 cc. of the culture-disinfectant mixture was removed from the test tube, 0.5 cc. inoculated into a tube containing about 11 cc. of blood broth, and the other 0.5 cc. portion inoculated into a tube containing about 11 cc. of fluid thioglycollate medium. At the ten minute interval 1 cc. portions or less, if the disinfectant was toxic for mice, of the culture-disinfectant mixture was injected intraperitoneally into white mice weighing 17-20 Gm. each. The temperature of medication was room temperature. After all subcultures had been made the tubes were thoroughly shaken and then incubated at 37 C. Subculture tubes which did not show growth were kept under observation for seven

days before discarding. Growth in the subculture tubes was checked microscopically and in some cases by streaking onto blood agar plates. Streptococci were demonstrated in all critical tubes. The heart's blood from some of the mice which died following the injection of each culture-germicide mixture was streaked on blood agar plates and hemolytic streptococcus colonies were demonstrated. Representative cultures isolated from the heart's blood cultures were demonstrated to be group A by the technic of Brown.¹⁶

Controls.—Comparable amounts of the germicides which were contained in the dose of germicide-culture mixtures were injected intraperitoneally into mice to prove that the mice were not killed by the germicide. Virulence of the culture was demonstrated by adding 1 cc. of culture to 10 cc. of sterile distilled water, allowing to stand at room temperature for ten minutes, then injecting 1 cc. into each of four mice. Hemolytic streptococci were demonstrated in the heart's blood

because the loop was unsatisfactory, and Tice and Pressman¹⁹ employed 0.05 cc. amounts. The toxicity of some of the compounds did not permit us to inject mice with more than 0.1 or 0.2 cc. The volume of culture-germicide mixture transferred by means of a pipet is arbitrary. By transferring larger volumes a more critical test is placed on the germicide, but this should not present an obstacle if the compound is an effective germicide.

EXPERIMENTAL

It would be very advantageous if cultures of virulent hemolytic streptococci could be grown in a blood-free culture medium with virulence of the culture maintained. The culture of hemolytic streptococcus strain C203M, recently passed through mice, was inoculated into the following five mediums: (1) extract broth containing 10 per cent horse blood, (2) Bacto-anaerobe medium, experimental, (3) Bacto-cooked meat medium, (4) Bacto-tryptose phosphate broth and (5) hydro-

after death of the mice. Representative cultures isolated from the heart's blood of the dead mice were demonstrated to be group A by the technic of Brown.¹⁶

The transferring of a measured amount of culture-germicide mixture to the subculture tubes and to mice differed from the standard technic of transferring one loopful, but we feel that it is desirable and advantageous. The standard loop is estimated to hold about 0.02 cc. By transferring a larger volume one has a better chance of transferring viable organisms if they exist in the culture-germicide mixture. This is desirable, as our results indicate that a minimum of four streptococcus organisms of the strain used were required to produce a fatal infection in mice. Garrod¹⁷ in 1935 pointed out that "an adequately large number of bacteria should be added to cultures in which bacteriostatic action is being studied." We found that a volume of 0.5 cc. could be employed conveniently in our *in vitro* tests. Tobie and Orr¹⁸ transferred inoculums of 0.02 cc. with pipets

lyzed casein medium. Serial transfers were carried through the mediums until the cultures had been grown in each medium for nineteen successive transfers. A

sixth medium, Bacto-thioglycollate medium, Brewer's formula, was also included, but contamination of the culture caused us to drop that medium from the series.

19. Tice, L. F., and Pressman, R.: Antiseptics of the Quaternary Ammonium Type in the Presence of Positive and Negative Gelatin, J. Am. Pharm. A. (Sc. Ed.) 34: 201-204 (Aug.) 1945.

When the growths in the nineteenth serial transfers in each medium were 24 hours old, serial dilutions of each culture were made in extract broth. One cc. of each dilution was inoculated intraperitoneally into each of 3 mice, and 1 cc. was made into a blood agar poured plate. The results are summarized in table 1.

The results summarized in table 1 indicate that extract broth containing 10 per cent horse blood satisfactorily supported growth of the hemolytic streptococci and the organisms possessed the highest virulence for mice. Mediums not containing blood were not as satisfactory.

For the work to be described it is necessary to have two culture mediums which will support growth of hemolytic streptococci equally well. One of the culture mediums must be capable of neutralizing the bacteriostatic action of mercurial compounds, and for this

ten minutes was not a disinfectant because mice injected with such mixtures invariably died. In all 16 out of 17 mice injected with such mixtures died. Mercurochrome 2 per cent and metaphen 1:500 failed to kill streptococci within an exposure period of even fifteen minutes when the culture-germicide mixtures were subcultured into thioglycollate medium, and they failed to protect all of the mice from fatal infections. When the cultures of streptococci were treated with the marketed concentrations of these compounds diluted 1:2 and then injected into mice nearly all of the mice died. Perhaps the reason that growth of the streptococci in the thioglycollate subculturing medium was not accompanied with killing of all the animals is that fewer organisms are needed to initiate growth in the culture medium than are needed to kill a mouse. This is evident from the data in tables 1 and 2.

TABLE 3.—Results* Obtained When Various Compounds Were Injected into Mice

And when mixtures of streptococci and these compounds were subcultured into blood broth and thioglycollate medium after intervals of exposure of 5, 10, and 15 minutes and the culture germicide mixture injected into mice after an exposure of ten minutes

Material	Dilution	Blood Broth, Minutes			Thioglycollate Medium, Minutes			Num- ber of Mice In- jected	Amount In- jected	Results
		5	10	15	5	10	15			
Mercurochrome 2 per cent	Undiluted	..	..	..	..	..	..	4	0.1 cc.	3 survived, 1 died 63 hours.
Mercurochrome 2 per cent	1:2	..	..	..	..	..	..	4	0.1 cc.	All survived.
Mercurochrome 2 per cent	Undiluted	—	—	—	+	+	+	4	0.1 cc.	1 died <15 hours, gram negative rod isolated from heart's blood. 1 died <15 hours, spreader isolated from heart's blood. 1 died 25 hours, no hemolytic streptococci isolated from heart's blood. 1 died 40 hours, hemolytic streptococci isolated from heart's blood.
Mercurochrome 2 per cent	1:2	—	—	—	+	+	+	4	0.1 cc.	All died <40 hours. Hemolytic streptococci isolated from heart's blood of all of the mice.
Metaphen 1:500.....	Undiluted	..	..	..	..	..	..	4	0.1 cc.	All survived.
Metaphen 1:500.....	1:2	..	..	..	..	..	..	4	0.2 cc.	All survived.
Metaphen 1:500.....	Undiluted	—	—	—	+	+	+	4	0.1 cc.	2 survived, 2 died. Heart's blood of 1 mouse cultured and hemolytic streptococci found.
Metaphen 1:500.....	1:2	—	—	—	+	+	+	4	0.2 cc.	1 died 23 hours. 2 died <40 hours. Hemolytic streptococci in the heart's blood. 1 survived.
Merthiolate 1:1,000.....	Undiluted	..	..	..	..	..	..	2	1 cc.	All survived.
Merthiolate 1:1,000.....	1:2	..	..	..	..	..	..	2	1 cc.	All survived.
Merthiolate 1:1,000.....	Undiluted	—	—	—	+	+	+	4	0.5 cc.	All died in 24 hours. Heart's blood of 2 mice cultured and hemolytic streptococci in both.
Merthiolate 1:1,000.....	1:2	—	—	—	+	+	+	4	0.5 cc.	3 died in 24 hours. 1 died in 48 hours. Heart's blood of 1 mouse cultured and hemolytic streptococci found.
Phenol 1:80.....		..	..	..	..	..	..	4	0.5 cc.	All survived.
Phenol 1:80.....		—	—	—	+	—	—	4	0.5 cc.	3 survived, 1 died ½ hour from trauma during injection.
Phenol 1:100.....		—	—	—	+	+	—	4	0.5 cc.	All survived.
Phenol 1:120.....		—	—	—	+	+	+	4	0.5 cc.	All survived.
Phenol 1:140.....		—	—	—	+	+	+	4	0.5 cc.	1 died 24 hours; 2 died <41 hours. Hemolytic streptococci isolated from heart's blood of all 3 mice. 1 survived.

* These results are from one experiment but are typical of the results usually obtained in the various tests which were made.
— = no growth; + = growth of the test organism. .. = toxicity test on disinfectants.

medium we selected Bacto-thioglycollate medium, Linden's formula. The other medium must be incapable of neutralizing such bacteriostatic action, and beef extract broth with the addition of various substances was tried. The results are summarized in table 2.

From the results summarized in table 2, beef extract broth containing 10 per cent horse blood supported growth of hemolytic streptococci C203M as well as did Bacto-thioglycollate medium, Linden's formula. The addition of 10 per cent blood to the extract broth was preferred to 0.2 per cent cerulose because of the ease of reading growth in the medium containing blood and because it is the medium in which the organisms are maintained in culture.

Typical results obtained from numerous experiments wherein the cultures of hemolytic streptococci were exposed to the action of the various compounds and then subcultured and also injected into mice are given in table 3. It can be seen that, if subculturing of the mercurial germicide-culture mixture into thioglycollate medium resulted in growth of the culture, the organisms are still capable of producing a fatal infection in the animal body. Merthiolate 1:1,000, aqueous, when allowed to act on a culture of hemolytic streptococci for

COMMENT

In a preliminary report of this work²⁰ we made the statement that metaphen 1:500 was germicidal in an exposure of ten minutes but not of five minutes. These results were obtained when the culture-germicide mixture was subcultured to blood broth and at the end of the experiment transfers were made from each subculture blood broth tube to a second tube of blood broth and to a tube of thioglycollate medium. The subculturing from the primary subculture tubes, as recommended by Shippen,⁶ does not give results as reliable as when the subcultures are made directly into a medium which will neutralize the bacteriostatic action of the mercurial compound as recommended by Brewer¹¹ and as required by the National Institute of Health¹⁴ in the sterility testing of biologic products. In this particular experiment only 1 out of 4 mice injected with the mixture of culture and metaphen 1:500 died, but in another experiment 2 out of 4 animals died. The marketed solution of a germicide should be more effective in destroying pathogenic organisms.

20. Morton, H. E.; North, L. L., and Engley, F. B., Jr.: In Vitro and In Vivo Studies on the Bacteriostatic and Bactericidal Actions of Mercurial Disinfectants on Hemolytic Streptococci, J. Bact. 50:125-126 (July) 1945.

Johnson and Meloney²¹ reported that merthiolate was ineffective in preventing contamination of blood plasma, and Morgan, Simmons and Riggs²² observed that organisms exposed to a concentration of 1:1,000 merthiolate for seven days at 5 C. proved viable when subcultured to thioglycollate medium. The longest period of exposure of hemolytic streptococci to merthiolate 1:1,000 was fifteen minutes at room temperature, and we always found the cultures viable when subcultured in thioglycollate medium. Although Graydon and Biggs²³ reported that the lag period may extend to weeks or even months when organisms are treated with sublethal doses of antiseptic, such as merthiolate, we observed no change in our subculture tubes between the second and sixth days of incubation, so terminated our observations on the sixth day. The results obtained within that period were obvious and satisfied the purpose of our experiment.

Finding that the marketed solutions of mercurochrome, metaphen and merthiolate failed to kill all the vegetative cells in a culture of hemolytic streptococci in vitro is not surprising in view of the results published by Hoyt, Fisk and Burde²⁴ and Nye.²⁵ It was to be expected that Green and Birkeland²⁶ would fail to find any therapeutic action when merthiolate (1:10,000 to 1:30,000) and metaphen (1:5,000 to 1:20,000) were applied to the chorioallantoic membranes inoculated with *Staphylococcus aureus*. In working with metaphen, mercurial M, merthiolate, mercurochrome and bichloride of mercury, Smith, Czarnetzky and Mudd²⁷ came to the conclusion that the activity of a mercurial antiseptic in serum is reduced to 0.33 to 0.007 per cent of its activity in saline solution. The marketed solutions of the three mercurials studied did not completely kill cultures of hemolytic streptococci in distilled water in an exposure of ten minutes, so any further reduction in antibacterial activity by the presence of serum would not leave much to be expected in the way of germicidal action. In spite of these facts the label on a bottle of "Solution Merthiolate, 1:1,000, Stainless" purchased as recent as June 1947 states that it is "a stable, stainless, organic mercury compound solution of high germicidal value, particularly in serum and other protein media." It is not highly germicidal and especially does not possess high germicidal value in the presence of serum and other protein mediums. The loss of antibacterial activity of mercurials in the presence of serum proves their incompatibility with serum. Not only is the antibacterial action of mercurial compounds much reduced in the presence of blood serum, but Waller²⁸ has found that a final concentration of 1:5,000 merthiolate destroyed the anti-Rh agglutinins in human serums.

The comparative in vitro studies of mercurochrome, metaphen and merthiolate on embryonic tissue cells and bacterial cells by Salle and Lazarus²⁹ cannot be ignored. These investigators found that metaphen, merthiolate and mercurochrome were 12, 35 and 262 times respectively more toxic for embryonic tissue cells than for *Staphylococcus aureus*. Nye²⁵ and Welch³⁰ also found the same three mercurial compounds more toxic for leukocytes than for bacterial cells. Not only is there the direct toxic action of the mercurial compounds on the cellular and humoral components of the animal body, but there is also the possibility of sensitization. Hollander³¹ has recently reported a case of contact dermatitis produced by tincture of merthiolate.

We wished to learn whether organisms put in a state of bacteriostasis by a mercurial compound were harmless if introduced into the animal body. It is quite obvious that they are not harmless. There is a good correlation between the growth of hemolytic streptococci in thioglycollate medium and fatal septicemia in mice. In view of our recent knowledge of disinfectants, we wished to learn what might be expected of the three most commonly advertised mercurial compounds. The marketed aqueous solutions of the three compounds mercurochrome, merthiolate and metaphen are not effective disinfectants because when virulent organisms are treated with the substances for as long as ten minutes and introduced into the animal body either intraperitoneally or intradermally, the animals are not protected from infection. The substances are not effective germicides, as cultures treated with them are still viable. Neither are the substances effective antiseptics, as they are incapable of preventing sepsis when the pathogenic organisms are exposed as long as ten minutes to the substances. It can be stated that the substances have a bacteriostatic action. The efficacy of employing a bacteriostatic agent for topical application is beyond the scope of this paper. We only wish to point out that a pathogenic organism placed in a state of bacteriostasis by a mercurial compound is still capable of producing a fatal septicemia if introduced into the animal body and capable of producing a localized infection if introduced into the skin.¹⁰

SUMMARY

The organomercurial compounds "mercurochrome," "merthiolate" and "metaphen," as supplied in aqueous solutions on the market, possess many shortcomings as disinfectants. Aqueous solutions of these compounds may not completely kill cultures of virulent hemolytic streptococci, in that mice receiving an intraperitoneal injection of the culture-germicide mixture, after ten minutes' exposure of the organisms to the drugs, usually die, and hemolytic streptococci can be isolated from the heart's blood after death of the mice.

Hemolytic streptococci, an example of non-spore forming pathogenic organisms, while in a state of bacteriostasis produced by a mercurial compound, are still infectious for the animal body. Bactericidal rather than bacteriostatic action of the compounds is necessary to prevent a generalized infection.

Reports in the literature indicate that these three organomercurial compounds are more toxic for embryonic tissue cells and leukocytes than for bacterial cells.

THE PHARMACEUTICAL-MEDICAL RESEARCH FOUNDATION

When the American Pharmaceutical Manufacturers' Association awarded its plaque to the American Medical Association on December 16, the occasion was signaled by an announcement of the formation of a new foundation to be supported in major part by the pharmaceutical industry, to be devoted to scientific research and to represent a joint effort of the pharmaceutical and medical professions. This foundation, to be called the Pharmaceutical-Medical Research Foundation, is to be modeled after the Nutrition Foundation, which already has a record of important contributions to the advancement of knowledge in that field. The Nutrition Foundation was developed largely through the interest of Mr. Charles Wesley Dunn, general counsel for the American Pharmaceutical Manufacturers' Association.

While many millions of dollars are spent annually in the United States on research of a practical and applied character, the comparative amounts expended on basic research are infinitesimal. Before controlling many of the diseases which still baffle medical science, extensive studies are required related to the chemical and physical changes that occur in tissues and to the physiology of the body—particularly concerning substances taken into the body and their ultimate fate. What part do childhood infections, nutritional deficiencies, fatigue and mental stresses play in the development of the degenerative diseases? These questions and many hundreds like them require positive answers. From such answers will come specific methods of diagnosis, prevention and treatment, which will mean increasing years of health and happiness for more and more persons.

A committee, including representatives of the pharmaceutical industry and the medical profession, was organized to establish the new foundation. The representatives from the pharmaceutical industry are Mr. S. DeWitt Clough, chairman of the board, Abbott Laboratories; Mr. A. H. Fiske, vice president, Eli Lilly & Company; Mr. Elmer H. Bobst, president,

William R. Warner & Co., Inc.; Mr. John L. Smith, president, Chas. Pfizer & Co., Inc.; Mr. S. Barksdale Penick Jr., president, S. B. Penick & Co.; Mr. M. C. Eaton, president, Eaton Laboratories, Inc., and Mr. Charles Wesley Dunn, general counsel for the American Pharmaceutical Manufacturers' Association. The representatives from the medical profession are the following officers of the American Medical Association: Dr. R. L. Sensenich, President-Elect; Dr. E. L. Henderson, chairman of the Board of Trustees; Dr. Ernest E. Irons, secretary of the Board of Trustees; Dr. Morris Fishbein, Editor of THE JOURNAL, and Dr. Austin Smith, secretary of the Council on Pharmacy and Chemistry. Dr. Sensenich is chairman of the committee.

The foundation will be a wholly public institution in purpose, conduct and service; its governing board will include distinguished representatives of the general public, in addition to leading representatives of the pharmaceutical industry and medical profession. The board will determine its program of scientific research, on the basis of a recommendation by an authoritative scientific advisory committee and the advice of an eminent scientific director. Much of the initial basic research sponsored by the foundation will be in the field of the degenerative diseases, where there is urgent need.

VOLUNTARY ACCELERATION OF HEART

According to Favill and White¹ only thirteen persons with the power to accelerate the heart beat were recorded in medical literature up to 1917. In only one instance were electrocardiographic studies made. Much discussion has been printed as to the mechanism of this acceleration, especially as to whether it is purely a removal of vagal influences or primarily an accelerator nerve action. The voluntary acceleration of the heart rate in the case reported by Favill and White began almost immediately after the subject had willed it to begin and one second after the command was given by the observer. The greatest acceleration recorded electrocardiographically in their case was 63 beats, from a rate of 98 to 161. Atropine in a dose of $\frac{2}{1,000}$ grain subcutaneously increased the heart rate from 82 to 105 in half an hour. The patient was able to increase his heart rate at the height of the atropine effect by 20 beats, the rate rising from 105 to 125. On a second occasion one hour after injection of $\frac{1}{50}$ grain of atropine, voluntary acceleration was attempted and resulted in an abrupt increase of the pulse rate from 140 to 168 per minute. With the removal of vagal action, the voluntary increase in the heart rate appears to be the result of the accelerator nerve action. There was a definite rise in blood pressure following the onset of voluntary tachycardia. The systolic pressure rose from 124 to 146 and the diastolic from 80 to

1. Favill, J., and White, P. D.: Voluntary Acceleration of the Heart Beat, *Heart* 6: 175, 1917.

110. Dilatation of the pupils occurred within one second after the word to accelerate the pulse was given. The acceleration appeared to depend on an effort of the will, and the strain was as tiring as that produced by holding up a heavy weight. Distinct relief was felt with the cessation of acceleration. Change in the situation of the pacemaker with the onset of acceleration was not apparent. The observers felt that the voluntary increase of the heart rate in their subject was the result in great part at least of the action of the accelerator nerve mechanism and that it was not due solely or chiefly to the withdrawal of vagal action. The changes in the electrocardiographic deflections during the acceleration were those which are known to occur when the sympathetic nerves are stimulated experimentally.

West and Savage² reported a young medical student who was apparently free from all physical and neurotic defects and who was able to increase his heart rate voluntarily. A radial tracing showed that the heart rate began to increase almost immediately after the word of command and reached its maximum after about ten heart cycles. The greatest voluntary acceleration recorded in this subject was one of 27 beats per minute. Pressure on the right vagus produced a prompt slowing of the heart rate from 72 to 48 beats per minute. The results following injection of atropine were at variance with those reported by Favill and White, who did not find reduction in the ability to accelerate. A definite and corresponding decrease in the sinus arrhythmia and the ability to accelerate occurred at the height of the atropine effect. Had atropine been given in sufficiently large dose to paralyze completely the vagus terminals, the ability voluntarily to change the rate would have been abolished, or nearly so. The investigators therefore believed that persons with higher degrees of voluntary increase in rate may be able to add accelerator stimuli to a primarily vagus release.

Carter and Wedd³ studied a man who for many years experienced attacks of paroxysmal tachycardia which he learned to cut short by a voluntary effort. He was able to initiate an attack of tachycardia as well as to control it without any evident muscular effort. The dominant rate of the pathologic rhythm in the attacks of tachycardia remained constant at approximately 200 beats per minute. Pressure over both the right and the left vagus failed to induce the slightest change in either the rate or the cardiac rhythm. While under the influence of atropine the man was unable to break through the rate, due to the cardiac escape, and thus induce a higher speed of the ectopic rhythm. That all inhibitory vagal control had been removed was evidenced by the failure to control the rate under

atropine subjectively and by the conspicuous physiologic effects of the drug. The reaction to atropine in this case is proof that the investigators were not dealing with an ectopic focus entirely removed from neurogenic control. Following partial recovery from the atropine effect, two hours after its administration, the man again was able to induce the pathologic rhythm and could retard slowly his rate of 106 down to 85 per minute. In view of the constant similarity of the ventricular complex, the constancy of the conduction time and the constant time relationship of the extrasystoles to the preceding ventricular contraction and the direction of the P wave, the authors assumed that they were dealing with an ectopic rhythm originating in the upper level of the atrium near the pacemaker, conspicuously under the control of subjective inhibitory reflexes but uninfluenced by vagal stimulation. They did not find demonstrable evidence of any accelerator influence or control over the tachycardia, in spite of the general inferences supporting such a view.

The case reported by Feil and his associates⁴ is interesting because of association with the Wolff-Parkinson-White syndrome. Their patient, a medical student, first learned voluntarily to dilate his pupils. After repeated experiences he was able to dissociate the effort to dilate his pupils and to concentrate on the will to accelerate his heart. He was subject to attacks of paroxysmal tachycardia five or six times a year. These attacks started and stopped suddenly and were unrelated to any effort at voluntary acceleration. The pressure on carotid sinus did not affect either acceleration or deceleration. An experiment to determine the ability of the subject to maintain sustained acceleration was performed. The control rate was 76; 1.12 seconds after the order "fast" was given the rate rose to 109, and in five cycles it rose to 146, an increase of 70 beats per minute. He was able to maintain acceleration for 1 minute and 55 seconds, the rate falling to 84 at the end of the experiment. The case is unique because of its association with anomalous ventricular excitation characteristic of the Wolff-Parkinson-White syndrome. Epinephrine and atropine given in physiologic doses did not prevent the ability of the subject to control his heart action. Epinephrine appeared to have an augmentive effect on acceleration. Drugs that increase vagus tone, such as digitalis, quinidine and ergotamine tartrate, did not prevent the acceleration and deceleration. Physical means of acceleration such as changes in respiration or muscular activity were not demonstrated. The electroencephalogram demonstrated that psychic activity preceded the acceleration. The diminution in the peripheral blood flow and the dilatation of the pupils point to the importance of the impulses by way of the sympathetic system. The authors concluded that the ability of the

subject to influence his heart rate was chiefly through sympathetic control, although inhibition and augmentation of vagus influences also played a part. This is in keeping with the idea that cardiac function results from the balance between the activities of the sympathetic and the parasympathetic divisions of the autonomic nervous system.

Current Comment

COR PULMONALE¹

Hypertrophy of the right ventricle of the heart, "cor pulmonale," occurs in acute, subacute or chronic form. The acute form is commonly caused by massive pulmonary emboli; death may result almost immediately. The subacute form, least frequent, is oftenest due to secondary carcinomatous infiltration of the perivascular lymphatics and of the pulmonary arterioles; occasionally the subacute lesion follows embolism of the smaller pulmonary vessels.¹ Similar changes in the right ventricle have been found in sickle cell anemia attended by multiple disseminated thromboses of the smaller pulmonary arteries.² Chronic cor pulmonale, commonest of the varieties, is associated with a greater number of anatomic changes. In 110 postmortem examinations³ enlargement of the right side of the heart was traceable to chronic obstructive emphysema in 72 (65.4 per cent). Other causes such as silicosis and bronchiectasis, tuberculosis, bronchial asthma, silico-tuberculosis, kyphoscoliosis and pulmonary arteriolar sclerosis were present less frequently in about the order named. In silicosis and bronchiectasis cor pulmonale occurs oftenest in cases of peribronchial and perivascular fibrosis rather than in the nodular fibroses that may accompany either of these diseases. In tuberculosis the hypertrophic changes in the right ventricle usually follow extensive sclerotic lesions in the lungs, while in asthma ventricular enlargement is apparently dependent on increased intravascular pressure associated with repeated paroxysms of expiratory dyspnea. In thoracic deformities, kyphoscoliosis and secondary emphysema seem to be the main factors in the production of pulmonary hypertension and hypertrophy of the right ventricle. With primary pulmonary arteriolar sclerosis, cases of pressure on the main pulmonary artery, organized vascular thrombi and schistosomiasis with parasitic invasion of the walls of the pulmonary vessels, diminution in the caliber of the vascular channels leads to increased resistance to the flow of blood and hence to hypertrophy of the right ventricle.

Cor pulmonale was found in 6.3 per cent of 890 post-mortem examinations of cardiac patients.^{3a} In 60 cases studied by Spain and Handler^{3b} cor pulmonale occurred oftenest in men between the ages of 50 and 65. According to Brill,⁴ the clinical features are those of the underlying pulmonary disease. Symptoms and signs include dyspnea, hemoptysis, cyanosis, polycythemia, clubbing of the fingers, engorgement of the veins of the neck, enlarged liver, generalized edema and increased venous pressure indicating failure of the right ventricle. In many instances, although the symptoms and signs of the underlying pulmonary disease merge almost imperceptibly into those of cardiac failure, the appearance of orthopnea and intensification in the degree of cyanosis are ominous portents of myocardial exhaustion.

CYANOSIS AS A SIGN OF ARTERIAL ANOXEMIA

Comroe and Botelho¹ believe that cyanosis is a poor guide for the detection of arterial anoxemia of slight to moderate degree. Stadie demonstrated that the arterial saturation in his pneumonia patients did not always correspond to the degree of cyanosis. Lundsgaard and Van Slyke have stated that approximately 5 Gm. of reduced hemoglobin must be present in 100 cc. of capillary blood to produce visible cyanosis. Utilizing the oximeter developed by Millikan, the authors¹ tested the ability of medical students and experienced clinicians to recognize the presence of arterial anoxemia by observing the appearance of cyanosis. Variable degrees of arterial oxygen saturation were obtained in normal subjects by making them inhale mixtures low in oxygen. The saturation was measured continuously by an oximeter. A total of 20 normal white men between the ages of 19 and 25 and 127 observers (105 medical students and 22 physicians) participated in this study. The majority of the 127 observers were unable to detect the presence of definite cyanosis until the arterial oxygen saturation fell to approximately 80 per cent; 25 per cent of observers did not note definite cyanosis even at arterial saturation levels of 71 to 75 per cent. The investigators state that cyanosis is seldom a reliable guide to slight or moderate arterial anoxemia and that other commonly used signs, such as rapid pulse and hyperpnea, are also unreliable. The extent of arterial anoxemia can be determined accurately in patients only by direct analysis of arterial blood. The oximeter cannot be employed to indicate the level of arterial oxygen saturation in cyanotic persons, since the instrument must be set for each at a known value. An arterial puncture can be performed, however, and a determination of oxygen saturation can be done quickly by the method of Van Slyke and Neill; the oximeter can then be set to this figure. Evaluation of therapy can be made easily by noting oximeter changes in response to the employment of oxygen by oropharyngeal catheter, tent, mask or pressure breathing.

Business Session—Reports, Committees—Election of Officers

RADIO PROGRAMS

The A.M.A.-N.B.C. radio program, "Doctors Today," which opened Dec. 13, 1947, is scheduled to run for twenty-six consecutive weeks at 3 p. m. each Saturday, Chicago time. The exact number of stations taking the program will be announced when available; the 1947 series "Doctors—Then and Now" was broadcast by approximately one hundred and forty stations coast to coast.

"Doctors Today" is a program based on timeliness and therefore subject to change. The following schedule is tentative. Announcement of changes will be made in THE JOURNAL whenever possible, but there may be times when the program broadcast will not coincide in subject or title with that previously announced.

Whenever possible programs canceled in favor of more timely ones will be broadcast later in the series.

Following is the schedule for programs now contemplated:

January 3, Cancer.
January 10, Care of the Chronically Ill.
January 17, Alcoholism.
January 24, Federal Control of Drugs
January 31, Urgent Need for Nurses.
February 7, Health in Rural Schools.

Council on Medical Service

THE RHODE ISLAND SOCIETY'S VOLUNTARY PREPAYMENT PLAN

The house of delegates of the Rhode Island Medical Society approved in September 1947 the report of the Insurance Plan Study Committee, including Drs. Rocco Abbate, chairman, Charles J. Ainsworth, J. Murray Beardsley, Charles' L. Farrell and Arcadia Giura.

The complete report of the committee comprises three parts: a statement of principles and objectives, master schedule of surgical indemnities and participating physician's agreement.

Surgical fee schedules are admittedly to be developed according to prevailing charges for a particular locality. The basic structure for the operation of the program is contained in the statement of "Objectives and Principles."

Objectives and Principles

The Rhode Island Medical Society establishes as its objectives: (1) to increase the extent to which voluntary insurance against the cost of medical care is made available to the people of the state of Rhode Island; (2) to increase the effectiveness of such insurance through the voluntary cooperation of its members; (3) to make such insurance available at the lowest practicable cost under competitive conditions, and (4) to safeguard the physician-patient relationship deemed necessary by the society to maintain and improve the high standards of medical care in the state of Rhode Island.

Insurance Program

To attain such objectives the society hereby sponsors a program of prepaid surgical and obstetric insurance on the following principles:

1. Injuries compensable under the Workmen's Compensation Law will not be covered in this program.
2. The Master Schedule of Surgical Indemnities shall serve as a standard for use in connection with this plan where services are rendered up to and including a semiprivate level, including such extra services as are deemed necessary by the surgeon; such schedule is subject to change by the society as conditions and experience warrant.
3. The society shall make a determined effort to obtain the consent of its members to participate in the plan. Participation shall mean the doctor's agreement with the society to accept for a minimum of one calendar year he amounts in the indemnity schedule as full payment for the procedures listed therein for persons coming within the defined income group and their dependents insured under policies endorsed by the society, as hereinafter set forth; provided such persons authorize that the benefits be paid by the insurance carrier direct to the physician.
4. The society shall make a determined effort to interest all duly licensed insurance companies and the Blue Cross in underwriting this plan. Insurance company as hereafter used refers to such a duly licensed insurance company or the Blue Cross.)
5. Persons who shall receive surgical service for the indemnity fee listed in the Master Schedule of Surgical Indemnities include (a) individuals whose gross incomes do not exceed \$2,000 per year and whose gross aggregate family incomes do not exceed \$3,000 per year and (b) individuals with dependents whose gross aggregate incomes do not exceed \$3,000 per year at the time of disability. Persons whose gross incomes exceed such limits shall have such indemnity fee applied toward the physician's total bill, with such persons liable for any additional fee charged by the physician. These income limits are subject to change by the society from time to time as warranted by conditions and experience.
6. Each insurance company desiring to have its policies approved under this program shall submit to the society the policy form or forms it plans to offer with the endorsement of the society; such policy forms may include coverage in excess of that required by the society for endorsement; provided, however, no policies shall be sold under this program before Jan. 1, 1948.
7. The society shall review the policy forms and, if it finds that the indemnity schedules and other provisions in such policies, except as hereinafter noted, meet the minimum standards of coverage and believes that the promotion and sale of such policies will contribute toward the attainment of the objectives of its program, the society shall forthwith grant its consent to the use by the company of the statement "The Benefits of this Policy are Accepted and Approved by the Rhode Island Medical Society" on such policy forms and in its advertising and promotional literature to be used in connection therewith; for the sake of simplicity, some of the less frequent types of procedures may be omitted from the printed fee schedule in such policy forms, with the understanding that the attached indemnity schedule shall govern for unprinted procedures.
8. All advertisements and promotional literature involving the society's name shall be submitted to the society at least fourteen days (excluding Sundays and holidays) before its intended use, and the use of any such material shall be subject to disapproval of the society on reasonable notice to the company.
9. The society shall be under no obligation whatsoever to review the premium rate or rates of those policies submitted for its approval under this program, since it is the desire of the society to permit such rates to seek their natural levels through competition; however, the society may request any company to furnish it with the rates at which the policies are to be or are being offered to the public, and the company shall comply with such request within a reasonable time.

10. The society may request experience and enrollment figures from any insurance company and the company shall comply therewith in reasonable time, but such statistics shall not be made public in any manner which will identify any of the statistics with any one insurance company without that company's consent.

11. An insurance company whose policies are approved under this plan shall not interfere with the insured's free choice of a physician.

12. The society shall not interfere (except as hereinafter provided in paragraph 16) with an insurance company's rights and obligations under the terms of the policy form endorsed by the society, provided, however, that payments made by the insurance company under such policy for procedures not listed in the attached indemnity schedule shall be subject to review by the society.

13. An insurance company whose policies are approved under this plan may at any time, on fourteen days' prior written notice to the society (Sundays and holidays excluded), cease to issue its policies with the society's endorsement. Thereafter, such company shall not use the endorsement of the society on any new policies issued or in advertising or promotional literature in connection therewith. In such event the society's endorsement of all outstanding policies of said company shall nevertheless continue until the next following anniversary date of issue of such policies.

14. The society may at any time, on fourteen days' prior written notice to an insurance company (Sundays and holidays excluded), withdraw its consent to the use of its endorsement of any policy form and in advertising and promotional literature in connection therewith. In the event of such withdrawal (a) the company shall cease forthwith to use such endorsement on all new policies on such forms and in advertising and promotional literature in connection therewith; (b) the society's endorsement of all outstanding policies of said company on said form shall nevertheless continue until the next following anniversary date of issue of such policies; and (c) the company shall have no cause of action against the society except on proof of malice.

15. An insurance company whose policies are approved under this program shall not be prevented thereby from issuing policies which are not endorsed by the society so long as such policies and the advertising and promotional literature in connection therewith do not use the name of the society.

16. An insurance company whose policies are approved under this plan shall not make it a condition of selling any policy form endorsed by the society that the prospective policy holder shall take any additional or other form of insurance.

17. A Health Insurance Committee of the society shall confer with the insurance companies on problems which arise in connection with this program, for the purpose of taking appropriate action on administrative matters, complaints of persons insured and/or participating doctors, and, if so authorized, to act in the name of the society to carry out these principles.

Comment

The responsibility for the medical aspects of the program rests with the members of the medical profession. The medical society reserves the right to amend the indemnity schedule and also to alter the income limits for those subscribers who are to be eligible for service benefits. Provision is made for payment to surgical assistants for certain surgical procedures.

The insurance mechanics are the responsibility of the cooperating insurance companies. The program is flexible in that it permits a variety of coverages. Companies wishing to offer benefits in addition to those set forth as the minimum may do so. Likewise, those subscribers who do not qualify for service benefits may buy additional protection if desired.

The Rhode Island Plan was developed jointly by the committee and representatives of the insurance industry. It is understood that sufficient companies are interested to assure a wide distribution of coverage. Present plans anticipate that the coverage will be offered to the public in January 1948.

Coming Medical Meetings

American Medical Association Interim Session, Cleveland, Jan. 5-8.
Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

Annual Congress on Industrial Health, Cleveland, Jan. 5-6. Dr. Carl M. Peterson, 535 N. Dearborn St., Chicago 10, Secretary.

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 9-10. Dr. Donald G. Anderson, 535 North Dearborn St., Chicago 10, Secretary.

National Conference on Rural Health, Chicago, Palmer House, Feb. 6-7.
Dr. F. S. Crockett, 535 N. Dearborn St., Chicago 10, Chairman.

American Academy of Orthopaedic Surgeons, Chicago, Palmer House, Jan. 24-29. Dr. Harold B. Boyd, 869 Madison Ave., Memphis, Tenn., Secretary.

American Society for Surgery of the Hand, Chicago, Jan. 23-24. Dr. Joseph H. Boyes, 1401 S. Hope St., Los Angeles 15, Secretary.

Southeastern Allergy Association, Richmond, Va., Jefferson Hotel, Jan. 17-18. Dr. Katharine B. MacInnis, 1515 Bull St., Columbia 49, S. C., Secretary.

GOVERNMENT SERVICES

ARMY

NEW COMMISSIONING PROCEDURES

Representatives of all Army general hospitals in the United States attended a two day conference early in December in the Surgeon General's Office on procedures in commissioning medical and dental officers under provisions of Public Laws 365 and 381, enacted by Congress last August. This meeting launched a special procurement campaign which, for the first time, permits original appointment of physicians and dentists in advanced grades up to and including colonel. Simultaneously, the Surgeon General announced establishment of a special procurement branch in the personnel division, whose function will be to expedite handling of all applications. Eligible to apply for commissions in the Regular Army are civilian physicians and dentists without previous military affiliation, as well as members of the Officers' Reserve Corps, National Guard and Army of the United States, whether on active or inactive duty.

With regard to rank, Army circular 51, which is effective December 15, prescribes that grades will ordinarily be determined by the applicant's age and minimum active professional practice (excluding internships), including residencies and post-graduate training as follows (years of active duty as a physician or dentist in the armed forces will be included as professional practice):

Grade	Medical Professional Practice	Dental Professional Practice	Maximum age
First Lieutenant	No years	No years	32 years
Captain	3 years	4 years	37 years
Major	10 years	11 years	42 years
Lieutenant colonel	17 years	18 years	48 years

Appointments in the grade of colonel will be reserved for those applicants who possess outstanding qualifications for special positions established by the Surgeon General as requirements necessitate. Information as to provisions applicable to medical and dental officers now on active duty is obtainable from their commands, the Adjutant General's Office, the procurement branch in the Surgeon General's Office and Army general hospitals, where screening centers have been established. Civilians and officers on inactive duty will apply direct to the Adjutant General, Attention: AGSO-R, Washington 25, D. C.

SHORTAGE OF SOCIAL WORKERS

Professionally qualified social workers who hold an officer's commission in the Organized Reserve Corps may make application for recall to active duty for an indefinite period, according to an announcement by Major Gen. Raymond W. Bliss, the Surgeon General. These officers will be recalled in the grade held prior to separation from the service, and they will be assigned to the neuropsychiatric services in general hospitals, training centers and disciplinary barracks. There is a critical shortage of trained officers social workers now on duty. Forms for submitting application may be obtained from local Reserve Officer Corps units or directly from the office of the Surgeon General, Department of the Army Washington, D. C.

NEUROPSYCHIATRIC SURVEY IN EUROPEAN COMMAND

The system used by U. S. Army hospitals for neuropsychiatric cases in Germany and Austria was recently surveyed by Dr. Franklin G. Ebaugh, professor of psychiatry, University of Denver, and Dr. William H. Everts, Philadelphia, both formerly Army neuropsychiatrists and now consultants to the Surgeon General. The tour included hospitals in Nuremberg, Wiesbaden, Munich and Vienna. They also investigated German and Austrian practice and teaching in neuropsychiatry.

CHEMICAL PLANT LEASED TO PENICILLIN MANUFACTURER.

The Department of the Army has leased for a period of twenty years the Vigo Plant at Terre Haute, Ind., to Chas. Pfizer & Company of Brooklyn for the production of antibiotics and other drugs and chemicals for civilian use. The Vigo Plant, built during the war, was formerly operated under the jurisdiction of the Army Chemical Corps. Leasing the plant for the manufacture of penicillin, streptomycin, antibiotics and other biologicals and chemicals for civilian use will effect extensive savings for the government in maintenance costs as well as the revenue received in rental.

NAVY

CONFERENCE ON GRADUATE TRAINING

The Reserve Consultants Board to the Bureau of Medicine and Surgery will meet at the National Naval Medical Center, Bethesda, Md., January 9. The board will discuss matters pertaining to the Graduate Medical Training Program and the American Specialty Board requirements for naval medical officers. Sixteen civilian doctors will be present: Lowell Coggeshall, University of Chicago (tropical medicine); Donald Hale, Cleveland Clinic (anesthesia); J. Roscoe Miller, Chicago (internal medicine); Winchell M. Craig, Rochester, Minn. (neurologic surgery); Paul Titus, Pittsburgh (obstetrics and gynecology); Joseph S. Barr, Boston (orthopedics); E. N. Broyles, Baltimore (otolaryngology); George M. Lyon, Huntington, W. Va. (pediatrics); Paul W. Greeley, Chicago (plastic surgery); F. J. Braceland, Rochester, Minn. (psychiatry and neurology); Wendell G. Scott, St. Louis (radiology); Howard K. Gray, Rochester, Minn. (surgery); Clark M. Johnson, University of California (urology); M. G. Westmoreland, Chicago, College of American Pathologists (medical education); Alphonse McMahon, St. Louis (internal medicine), and A. C. Ivy, University of Illinois, Chicago, representing the preclinical sciences.

GRADUATE AVIATION MEDICAL EXAMINERS

Twelve naval medical officers received diplomas as aviation medical examiners at graduation exercises at the Naval Air Station, Pensacola, Fla., Dec. 5, 1947. The graduates completed three months of the Flight Surgeon's Course in classroom, laboratory and field work at the Naval School of Aviation Medicine. Capt. William Sinton, U. S. Navy, Commanding Officer of the Naval Air Station, gave the commencement address.

The naval medical officers graduated as aviation medical examiners were: Comd. Ross B. Lautzenheiser (MCR), U. S. N. R.; Lieuts. (jg) (MCR) Nathaniel M. Cohen, U. S. N. R.; Charles H. Crane, U. S. N. R.; Frederick P. Dale, U. S. N. R.; Richard E. Lieurance, U. S. N. R.; James W. Lynn Jr., U. S. N. R.; Ramon A. Mouton (MC), U. S. N.; Lieuts. (jg) (MCR) Doak Mudd, U. S. N. R.; Harold M. Peacock, U. S. N. R.; George M. Rhodes, U. S. N. R.; Leon J. Tune, U. S. N. R., and Robert H. Whittlesey, U. S. N. R.

The next class for flight surgeons and aviation medical examiners begins on Jan. 5, 1948.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CONNECTICUT

Personal.—Dr. Parker M. Cort, Hartford, on November 7 retired as associate medical director of Aetna Life Insurance Company. He had been with the company since 1926.

Smallpox Vaccination Guaranteed.—According to a document recently uncovered by the Connecticut Historical Society, in May 1805 Dr. Vine Utley wrote the following receipt on the payment for services to the entire family of Capt. William Brainard 2d of Westchester, whose family Dr. Utley had vaccinated against smallpox: "Received of Capt. William Brainard 2d, \$13 by note being in full for vaccinating himself, wife and children . . . and promise that if any of them shall take the smallpox at any time hereafter to pay all necessary expense in carrying them through said disease." All the family lived to a ripe age.

State Society Aids Graduate Program.—A broad program of postgraduate education is planned by the Yale University School of Medicine, New Haven, under a new committee consisting of Dr. Herbert Thoms, professor of obstetrics and gynecology, chairman; Dr. Milton C. Winternitz, Anthony N. Brady professor of pathology; William U. Gardner, Ph.D., professor and chairman of the department of anatomy; Dr. David M. Kydd, associate professor of medicine, and Dr. Creighton Barker, executive secretary of the Connecticut State Medical Society. To further this program the house of delegates of the State Medical Society at their recent semiannual meeting approved a grant of \$10,000 to the medical school for a period of two years.

ILLINOIS

Cancer Diagnostic Clinic in Waukegan.—A state-aided cancer diagnostic clinic has been opened at Victory Memorial Hospital, Waukegan. Clinic sessions are held every Thursday morning at 9 a. m. Dr. John C. McCarter is serving the new clinic as pathologist. This clinic brings to seventeen the number of such centers in operation throughout the state. Any resident of Illinois who has symptoms suggestive of cancer may arrange through his attending physician for admission to any one of the diagnostic clinics.

Joint Fund to Help Train Country Doctors.—The Illinois State Medical Society and the Illinois Agricultural Association have set up a medical training program based on a fund to be established by a contribution of \$50,000 each. From this fund loans will be made to accepted medical students at the rate of \$1,000 a year to a maximum of \$5,000 per student. The program will be administered by a "Farmer and Doctor Loan Fund Board" composed of three representatives of each organization.

A student seeking a loan under the plan must (1) agree to return to a town of less than 5,000 population in his home county for general practice; (2) apply from his native county and be unable to finance his training but free of debt; (3) be recommended in writing by both the local medical society and farm bureau; (4) pass the aptitude tests of the University of Illinois Medical School or the equivalent; (5) take his training in an approved medical school; (6) repay money advanced from the fund in five annual payments at 2 per cent interest after he begins to practice; take out a ten year term life insurance policy for \$5,000 payable to the board, premiums to be paid by the board from money lent the student during his training and by the beneficiary thereafter until the loan is repaid in full, and (7) repay the loan and accrued interest at once if he abandons his medical training.

Four new students will be accepted each school year beginning in the fall of 1948.

Chicago

University Appointment.—Dr. Jules H. Last, recently released from army duty with the rank of captain, has been appointed an assistant professor in the department of pharmacology and toxicology at the University of Illinois. Dr. Last conducted nutritional studies in the service. He received his doctor of philosophy degree at the University of Chicago, 1941, and his medical degree at the University of Illinois, 1944.

Lecture on Cirrhosis of the Liver.—The North Side Branch of the Chicago Medical Society will hear Dr. Russell S. Boles, University of Pennsylvania School of Medicine, Philadelphia, on "Modern Conception of Cirrhosis of the Liver" at its regular meeting at 8 p. m. January 8 in the Drake Hotel. The meeting will be preceded by a fellowship gathering at 5:30 and dinner at 6:30. Reservations should be made by calling Central 7764.

Dr. Cowdry to Give the Fenger Lecture.—The twelfth Christian Fenger Lecture of the Institute of Medicine of Chicago and the Chicago Pathological Society will be delivered at the Palmer House on Monday evening, January 12, by Edmund V. Cowdry, Ph.D., professor of anatomy, Washington University School of Medicine, St. Louis, and director of research, Barnard Free Skin and Cancer Hospital, St. Louis, on "Expectations in Cancer Research."

Grants for Cancer Research.—Two gifts of \$100,000 each have been made to the University of Chicago School of Medicine by Mr. and Mrs. Charles H. Worcester, Chicago. The gifts are to be used to provide facilities for cancer research, for which the Cancer Research Foundation of the university is presently conducting a campaign for \$2,570,000. The gifts of Mr. and Mrs. Worcester are the second provision they have made for the study of cancer at the University of Chicago. In September 1944 they gave \$400,000 to establish the Charles H. and Mary F. S. Worcester Fund for cancer research at the university.

KANSAS

Research in Cardiac Physiology.—The Kansas State Emergency Fund Commission has made a grant of \$10,000 to the University of Kansas School of Medicine, for research in cardiac physiology. The grant was made to: Drs. Paul W. Schafer, department of surgery; Mahlon H. Delp, department of medicine, and Paul H. Lorhan, department of anesthesiology.

Appoint Director of Mental Hygiene Division.—The Kansas State Board of Health has appointed Dr. Edgar W. Warren II, since January 1945 a fellow of the Menninger Foundation, as director of the newly established Mental Hygiene Division. Dr. Warren was graduated at Yale University School of Medicine, New Haven, Conn., in 1936 and was a member of Yale University department of student health from 1938 to 1941, when he joined the Louisiana State Department of Health; from 1943 to 1945 he was on the staff of the Ochsner Clinic, New Orleans.

MAINE

Biologic Research Facilities.—At Salsbury Cove the Mount Desert Island Biological Laboratory, which is celebrating its fiftieth birthday this summer, offers its facilities for research and study in biology between June 15 and Sept. 15, 1948. A newly equipped laboratory for the study of problems in tissue growth is under the supervision of Philip R. White, Ph.D. Persons desiring to work with Dr. White should first address their inquiries to him at the Institute for Cancer Research, Girard and Corinthian Avenues, Philadelphia 30.

Grant to Rebuild Laboratory at Bar Harbor.—The National Advisory Cancer Council of the U. S. Public Health Service in December awarded a grant of \$250,000 to aid in rebuilding the Roscoe B. Jackson Memorial Laboratory, Bar Harbor, which was destroyed by forest fire some time ago. This was the first substantial construction grant ever given by the National Advisory Cancer Council and was contingent on the securing of further funds from other sources to complete the building, which will cost an estimated \$650,000. Previously the Damon Runyan Memorial Fund for cancer research donated \$50,000. Clarence C. Little, Sc.D., has been director of the laboratory since 1929.

MINNESOTA

Society News.—The Ramsey County Medical Society at a meeting December 22 was addressed by Dr. Charles E. Rea, St. Paul, on "Is Hormonal Therapy of Value in Treatment of Undescended Testicle?" and Dr. John P. Medelman, St. Paul, on "Pulmonary Fibrosis."

Drug Store Depots.—The Bureau of Health of the city of St. Paul has selected fourteen drug stores to serve as depots where specimens of sputum and gastric contents may be left by physicians and picked up by the Bureau of Public Health for examination and report.

Blood Pressure Study on Business Men.—Three hundred St. Paul and Minneapolis businessmen between the ages of 45 and 54 are serving as test subjects in a ten year study of high blood pressure. The study, which is under way at the University of Minnesota, will attempt to determine whether habits of diet and exercise affect diseases of the heart and blood vessels.

NEW YORK

State to Operate Sanatorium.—According to newspaper reports the state has agreed to take over the county-operated Onondaga Sanatorium for the tuberculous next April 1 as the first step toward integration of tuberculosis treatment in the state's plan to eradicate the disease within twenty years through free hospitalization. The two hundred and fifty bed sanatorium will serve as a research and training center and will work closely with Syracuse University College of Medicine.

Hearing Aid for Children.—The New York League for the Hard of Hearing has begun a project in fitting hearing aids and in giving acoustic training for young children through cooperation of the Greater New York Fund, the Hecksher Foundation for Children and hearing aid manufacturers and dealers. The project includes preliminary audiometric study, hearing aid trials, acoustic training and follow-up at home and at school. About 100 children of the Greater New York area between 4 and 12 years of age will be admitted for fitting on recommendations from an otologist. Two lessons a week will be given at the league, plus home work supervised by parents and training at school. The league still needs funds to pay for additional hearing aids for indigent children, to secure a consulting psychologist and to pay clerical help.

Postgraduate Lectures.—The Medical Society of the State of New York in cooperation with the New York State Department of Health has arranged postgraduate lectures as follows: On January 15 the Geneva Academy of Medicine will hear Dr. Foster Kennedy, New York, speak on "Nervous Conditions Associated with Allergy," and on February 19 Dr. Wesley T. Pommerehne, Rochester, N. Y., on "Dysmenorrhea." Lectures will be held at the Seneca Hotel, Geneva, at 8:30 p. m.

Clinton County Medical Society will hear three lectures at 8:00 p. m. in the Champlain Valley Hospital Nurses Home, Plattsburg: January 15, Dr. Frederick T. Schantz, Buffalo, "Treatment of Persistent or Recurrent Dyspnea"; February 19, Dr. George H. Marcy, Buffalo, "Treatment of Low Back Pain," and March 18, Dr. Abraham H. Aaron, Buffalo, "Treatment of Epigastric Distress Following Meals."

Four lectures have been arranged for the Richmond County Medical Society in the auditorium of the U. S. Marine Hospital, Stapleton, Staten Island, at 4:30 p. m.: January 9, Dr. Russell L. Cecil, New York, "Treatment of Chronic Arthritis"; January 16, Dr. Carl T. Javert, New York, "Clinical and Obstetric Significance of the Rh Factor," and January 30, Dr. Thomas H. McGavack, New York, "Treatment of Hyperthyroidism."

New York City

Personal.—Dr. Charles E. Lyght, for five years director of health education, National Tuberculosis Association, on December 1 joined the staff of the Medical Division of Merck & Co., Inc., Rahway, N. J.

Harvey Lecture.—John F. Enders, Ph.D., associate professor of bacteriology and immunology, Harvard Medical School, Boston, and chief of the research division of infectious diseases, Children's Hospital, Boston, delivered the third Harvey Lecture of the current series at the New York Academy of Medicine December 18 on "Virus as Antigen With Special Reference to Mumps."

Annual President's Dinner.—The Medical Society of the County of Kings and the Academy of Medicine of Brooklyn will hold their fourth annual President's Dinner January 29 at the Columbus Club, 1 Prospect Park West. Dr. Louis H. Bauer, president of the Medical Society of the State of New York, will present the President's Medal and Scroll to Dr. Abraham Koplowitz.

Symposium on Diagnosis of Virus and Rickettsial Infections.—The New York Academy of Medicine, under the auspices of the section on microbiology, will present a symposium on the Diagnosis of Virus and Rickettsial Infections Thursday evening, January 29, and Friday afternoon and evening, January 30. Dr. Frank L. Horsfall is chairman of the symposium. Dr. Gregory Schwartzman is chairman of the section and Dr. Harry Most is secretary.

Hospital Establishes Rehabilitation Clinic.—Beth Israel Hospital has established a rehabilitation clinic designed for the treatment of patients disabled by cerebrovascular accidents and allied disorders. The purpose will be to treat and train such persons, the majority of whom would be in the upper age brackets and who also suffer from hardening of the arteries and high blood pressure, to live useful lives within the limits of their disability. The clinic eventually plans to broaden the program to include other types of disability. At present, admission to the new service will be limited to ward and clinic patients.

PENNSYLVANIA

Establish Bone Bank.—A bone bank to provide a constant supply of bone for grafting operations has been established at the George F. Geisinger Memorial Hospital, Danville. The bank was set up on the recommendation of Dr. Leonard F. Bush, head of the hospital's orthopedic department. Bone obtained from operations in which surplus bone is removed is sterilized and kept in a deep freeze unit at 10 F. (—12 C.) until needed. Several successful bone-grafting operations have already been performed with the use of bone from the bank.

WEST VIRGINIA

Dr. Gerhardt Goes to New York.—Dr. Paul R. Gerhardt, Charleston, director of the division of cancer control, state health department, since July 1944, has resigned to become director of the New York State Health Department's division of cancer control, with headquarters in Albany. Dr. Gerhardt, a graduate of the University of Wisconsin Medical School, Madison, was engaged in general practice in Boone County for three years before accepting appointment to the state's Bureau of Medical Service in 1942.

Mental Hospital Recommended.—The Mental Hygiene Committee of the West Virginia State Medical Association has recommended to the council that an appropriation be sought at the session of the legislature in 1949 for the construction of a new mental hospital in West Virginia and of a separate hospital for the feeble-minded and the epileptic. The committee plans to organize a state mental hygiene society, and the chairman, Dr. Oscar B. Biern, Huntington, has been directed to arrange for an organization meeting to be attended by representatives of the association's twenty-nine component societies. The meeting will be held in Charleston early in the spring.

Premature Baby Nursery.—A nursery at the Herbert Thomas Memorial Hospital in South Charleston, established under the auspices of the state health department, will open in January to offer services to doctors in the care of premature babies in Kanawha County. Although no charge will be made, parents will be permitted to pay a part or all of the expenses if they so desire, refund being made to the division of maternal and child health for the expenses incurred. The personnel will consist of four local pediatricians and three nurses. Special training was given the nurses by the state health department. A room was donated by the hospital. A special ambulance unit will be available, and the Charleston Fire Department will provide the driver.

The project was made possible through an outright grant from the Children's Bureau of the Federal Security Agency. West Virginia is one of four states providing this type of service. The nursery is patterned after the Chicago program.

WISCONSIN

Narcotic Violation.—Dr. Jerome F. McDowell, formerly of 1024 Main Street, Racine, now in Batavia, N. Y., pleaded guilty to an indictment charging violation of the Federal Narcotic Law and recently was sentenced to one year and one day. The sentence was suspended, and he was placed on probation for a period of three years.

New State Board Members.—Dr. John W. Prentice, Ashland, has been appointed a member of the Wisconsin State Board of Medical Examiners to succeed Dr. Raymond Arveson, Frederic, for a term ending July 1, 1951. Dr. Alvin G. Koehler, Oshkosh, has been appointed by the governor to the State Board of Medical Examiners, succeeding the late Dr. Jessie P. Allen of Beloit, for a term also expiring July 1, 1951.

PUERTO RICO

Annual Meeting of Puerto Rico Medical Association.—The annual meeting of the Puerto Rico Medical Association was held December 10-12 in San Juan with a large number of American and foreign physicians participating. New directors elected for 1948 are Dr. Manuel A. Astor, president; Dr. Juan Basora Defillo, secretary, and Dr. Manuel Guzmán Rodríguez, speaker of the house of delegates.

Delegates voted to take measures to prevent nonspecialists from advertising their services as specialists. Likewise, a closer supervision will be observed on newspaper advertising covering medical services.

In recognition of over fifty years of continuous service in the medical profession of the island, the meeting was held in honor of Drs. Manuel Quevedo Báez, founder of the association, J. A. Franco Soto, Isaac González Martínez and Vicente Roure. A diploma was delivered to each of these members by Dr. Victor Gutiérrez Ortiz.

GENERAL

International Bulletin Discontinued.—The *Monthly Bulletin* of the International Office of Public Hygiene, published uninterruptedly since 1909, has been discontinued since the International Office of Public Hygiene is to be taken over by the World Health Organization or its Interim Commission. The last number was October-November-December, 1946.

Medicolegal Congress.—A Medicolegal Congress will be held at the Sheraton-Coronado Hotel, St. Louis, January 19-21 under the auspices of the Board of Police Commissioners of St. Louis. Subjects under discussion include the psychopathic personality as a social and psychiatric problem, blood grouping, use of blood test in disputed parentage, the barbiturate problem and subdural hematoma.

Midwest Radiologic Conference.—The annual Midwest Radiologic Conference will be held at the Hotel Schroeder, Milwaukee, February 6-7. The dinner speaker on Friday evening, February 6, will be Dr. Robert R. Newell, Stanford University School of Medicine, San Francisco. Inquiries may be addressed to Dr. Abraham Melamed, Secretary, Milwaukee Roentgen Ray Society, 425 East Wisconsin Avenue, Milwaukee 2.

Oral Pathologists to Meet.—The American Academy of Oral Pathology will hold its second annual meeting at the Hotel Stevens, Chicago, Sunday, February 8. Among the speakers will be: Dr. Carl W. Waldron, Minneapolis; B. O. A. Thomas, D.D.S., Seattle; Edward Stafne, D.D.S., Rochester, Minn.; Hamilton B. G. Robinson, D.D.S., Columbus, Ohio; Barnett Levy, D.D.S., St. Louis; Irving Glickman, D.D.S., Boston; Henry Goldman, D.D.S., Boston; Lester R. Cahn, D.D.S., New York; Herman Becks, D.D.S., San Francisco, and Dr. Myron Aisenberg, Baltimore.

Conference of Professors of Preventive Medicine.—At the recent annual meeting of the Conference of Professors of Preventive Medicine, Dr. Henry E. Meleney, Hermann M. Biggs professor of preventive medicine and chairman of the department at the New York University College of Medicine, New York, was elected president for the next year. A mimeographed directory of persons engaged in teaching preventive medicine and public health in the eighty-eight medical schools in the United States and Canada was issued at this meeting. Copies may be obtained by writing to Dr. Thomas D. Dublin, Secretary, 248 Baltic Street, Brooklyn 2.

American College of Surgeons Meetings.—Six sectional meetings of the American College of Surgeons have been announced. Each meeting will last two days and will include conferences for hospital personnel as well as sessions for the members of the medical profession, and a symposium on cancer will follow a dinner meeting on the first evening. Panel discussions led by authorities in each field of surgery will be held each morning and afternoon. The list of meetings is as follows: Toledo, January 20-21, Commodore Perry Hotel; Atlanta, January 26-27, Ansley Hotel; Oklahoma City, January 30-31, Oklahoma Biltmore Hotel; Denver, March 1-2, Cosmopolitan Hotel; Minneapolis, March 15-16, Hotel Nicolet, and Halifax, May 17-18, the Nova Scotian.

Winners of Writing Awards.—For writing the year's best newspaper and magazine science series, George A. Keaney of the *New York World-Telegram* and Steven M. Spencer, associate editor of the *Saturday Evening Post*, on November 28 were named winners of \$1,000 prizes in the annual competition held by the American Association for the Advancement of Science for the George Westinghouse Science Writing Awards. Mr. Keaney received his award for a series of five articles printed last March 18 to 22 dealing with research in blood transfusions, blood substitutions to rescue infants doomed by Rh factor incompatibility, validity of paternity blood tests and proteins in blood. Mr. Spencer's prize-winning article, "New Hope for the Anemic," which appeared in the December 14, 1946, *Saturday Evening Post*, described the painstaking discovery and subsequent success of folic acid in the treatment of anemia.

International College of Surgeons.—The sixth International Assembly of the International College of Surgeons will be held in Rome, Italy, May 16-23, under the presidency of Professors Raffaele Bastianelli and Raffaele Paolucci of Rome and Mario Dogliotti of Turin. Scientific meetings and exhibits and visits to the universities of Turin and Milan have been arranged, together with tours to other medical centers. Information may be obtained from Dr. Max Thorek, General Secretary, 850 West Irving Park Road, Chicago 13. For travel information, address the All Nations Travel Bureau, 38 South Dearborn Street, Chicago. Those desiring to present scientific papers should address Dr. Karl Meyer, Cook County Hospital, Chicago; Dr. Henry W. Meyerding, Mayo Foundation, Roches-

ter, Minn., or Dr. Herbert Acuff, Acuff Clinic, 514 West Church Street, Knoxville, Tenn. Those from Canada should direct inquiries to Dr. Lyon Appleby, 925 West Georgia Street, Vancouver, B. C.

Annual Dinner of Vitamin Foundation.—More than one hundred and fifty notables in the field of medicine, public health, science and pharmacy were welcomed by Dr. Theodore G. Klumpp, New York, chairman of the board of governors, to the second annual dinner of the National Vitamin Foundation, Waldorf-Astoria Hotel, New York, December 12. Dr. Klumpp called for increased financial support of the foundation's research activities and the creation of additional projects in nutrition research. Mr. Basil O'Connor, national chairman of the American Red Cross, concluding his address said: "We must not lose sight of the primary objective of nutrition research—a complete understanding of the requirements of man to the end that his health and well-being may be materially improved. Buoyant health, a more productive life, sturdier children with a greater capacity for learning and achieving the worth while things of life, these are the promises held out by nutrition research pointing to a way of life in which man may more nearly become master of his own destiny." Dr. Robert S. Goodhart, New York, scientific director of the foundation, outlined vitamin research activities sponsored in hospitals and universities through the foundation's grants-in-aid, stating that during the past year more than \$50,000 had been voted for these continuing studies.

CANADA

Society News.—At a regular meeting of the Montreal Medico-Chirurgical Society January 9 at the society rooms, Montreal, Dr. Robert R. Linton, Brookline, Mass., will deliver an address entitled "Venous Thrombosis and Pulmonary Embolism."

Health Week February 1-7.—The Health League of Canada has designated February 1-7 as the country's fourth annual National Health Week. All organizations have been asked to assist in organizing local Health Week committees and in arranging for special meetings at which their own organization would feature health lectures and show appropriate films.

CORRECTION

Use of BAL in Lead Poisoning.—In the article by Dr. James G. Telfer in *THE JOURNAL*, Nov. 29, 1947, in the twenty-sixth line, second column, page 836, the figure 0.150 Gm. should have been 0.150 mg.

Hormone Metabolism in the Target Organs.—In line four of Dr. Arno B. Luckhardt's letter to the Editor in *THE JOURNAL*, Dec. 13, 1947, page 1025, the word "secretion" was a typographic error and should have been "secretin."

Marriages

FRANK PAGE SMITH, Easley, S. C., to Miss Thora Dagny Mykland of West Des Moines, Iowa, Nov. 28, 1947.

WILLIAM ROBERT WOOLNER, New York, to Miss Patricia Nanon Newman of Ridgefield, Conn., Nov. 13, 1947.

BENJAMIN STRAWBRIDGE PERKINS, Conshohocken, Pa., to Miss Helen Dales Walburn in Radnor, Sept. 16, 1947.

JAMES MICHAEL O'LEARY, Altoona, Pa., to Miss Patricia Ann McCann of Johnstown, Pa., Oct. 18, 1947.

ADRIAN BRODEY, Woodmere, L. I., N. Y., to Miss Sylvia Redlich of Mount Vernon, Aug. 3, 1947.

HAROLD L. NOBLE to Dr. ELLENETTA C. BEACHLEY, both of Washington, Pa., in October 1947.

HAROLD MARKS, San Mateo, Calif., to Dr. OLIVE IRENE MOE of Tacoma, Wash., Nov. 7, 1947.

JOHN D. GILLAND JR. to Mrs. Elizabeth Dove Manly, both of Kingstree, S. C., Nov. 11, 1947.

HERBERT K. BLOOM, Everett, Mass., to Miss Berenice Theresa Doherty of Boston, Nov. 1, 1947.

AUGUST F. DARO, Chicago, to Mrs. Maryann Major at Highland Park, Ill., Nov. 29, 1947.

ANTON G. KOVARY JR., Flushing, N. Y., to Miss Rose Wiesel of Maspeth, Oct. 25, 1947.

DICK M. NISBET, Eaton, Ohio, to Miss Charlotte Ann Monroe in Howell, Mich., recently.

Deaths

James Archer O'Reilly * director of the department of orthopedic surgery at St. Louis University School of Medicine, died in St. Luke's Hospital in St. Louis, Dec. 5, 1947, aged 68. Dr. O'Reilly was born in St. Louis Sept. 24, 1879. He received his A.B. in 1902 and his M.D. from Harvard University, Boston, in 1906. He served an internship at the Carney Hospital, Boston, and later became assistant orthopedist at the Children's Hospital and the Massachusetts General Hospital. From 1907 to 1910 he was instructor in orthopedic surgery at St. Louis University School of Medicine, then became associate professor of clinical orthopedic surgery at Washington University School of Medicine. During World War I he was orthopedic adviser to draft boards and served again in that capacity during World War II.

In 1933 he returned to St. Louis University as associate professor of orthopedic surgery. He had long been active in the work of the American Medical Association, serving the Section on Orthopedic Surgery as secretary from 1922 to 1926 and as chairman in 1927-1928, and as a member of the House of Delegates from 1931 to 1933 and from 1940 to 1947. He was a specialist certified by the American Board of Orthopedic Surgery. He was largely responsible for the development of the Missouri and St. Louis societies for crippled children, serving as president of the state group from 1930 to 1946, when he became chairman of the board. He had been president of the St. Louis society since its founding. A member of the board of trustees for the National Society for Crippled Children and Adults, Inc., since 1930, he was cited by this group in 1944 for distinguished service to the handicapped. He was a member of the American Orthopedic Association, Clinical Orthopedic Society, American Academy of Orthopedic Surgeons, Southern Medical Association and American Rheumatism Association and a fellow of the American College of Surgeons. In 1919 he was a member of the University City Board of Health. He was a member of the advisory committee of the State Division of Rehabilitation, department of public schools, of the boards of the Occupational Therapy Workshop and St. Louis School for Occupational Therapy, and of the board of regents of the State Cancer Hospital in Columbia. From 1930 to 1935 he headed a Red Cross Committee on Vocational Rehabilitation. Dr. O'Reilly was orthopedist to St. Mary's Group of Hospitals, and to De Paul Hospital. He served as a consultant to the St. Louis City Hospital, St. Mary's Infirmary and St. Luke's Hospital. He was a former president of the St. Louis Little Theatre, an officer of the Volunteer Film Association, the Air Board and the Charities Committee of the Chamber of Commerce. In his writings Dr. O'Reilly consistently stressed the need of total rehabilitation for the handicapped.

Clarence Gaines Toland * Los Angeles; born in Valley Mills, Texas, Aug. 17, 1875; University Medical College of Kansas City, Mo., 1901; clinical professor of surgery at the University of Southern California School of Medicine; at one time affiliated with the Mayo Clinic in Rochester, Minn.; during World War I a major in the medical corps of the U. S. Army, serving for a time as chief of the surgical staff in the Letterman General Hospital in San Francisco; member of the founders group of the American Board of Surgery; member of the House of Delegates of the American Medical Association, 1934-1935; past president of the California Medical Association, Mayo Foundation Alumni Association, Los Angeles Surgical Society, Los Angeles County Medical Association and the Western Surgical Association; member of the Los Angeles Academy of Medicine, California Heart Association, American Surgical Association and the Pacific Coast Surgical Association; fellow of the American College of Surgeons; member of the staffs of St. Vincent's and Good Samaritan hospitals; died Oct. 2, 1947, aged 72, of heart disease.

Clarence Henry Smith * New York; born in Bandon, County of Cork, Eire, Jan. 17, 1875; University and Bellevue Hospital Medical College, New York, 1899; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology, American Laryngological, Rhinological and Otolological Society and the American Otolological Society, Inc.; fellow of the American College of Surgeons; served on the faculty of the New York Post-Graduate Medical School and Hospital; formerly a vice president of the New York Otolological Society and a founder of the Bronx Otolological Society; secretary and director of the Physicians Mutual Aid Association for many years; affiliated with the Union, Bronx, Mother Cabrini, St. Elizabeth's, Manhattan Eye, Ear, Nose and Throat and Morrisania City hospitals and the Bronx Eye and Ear Infirmary; died Oct. 6, 1947, aged 72, of carcinoma.

Laurence Gibbons Alexander, Carrsville, Ky.; University of Nashville (Tenn.) Medical Department, 1904; member of the American Medical Association; past president of the Livingston County Medical Society; died Sept. 21, 1947, aged 66, of myocarditis and hypertension.

Jessie Petrie Allen * Beloit, Wis.; the Hahnemann Medical College and Hospital, Chicago, 1904; served on the state board of medical examiners; on the staff of Beloit Municipal Hospital; died Oct. 12, 1947, aged 69, of coronary occlusion.

William J. Anderson, Meridian, Miss.; University of Tennessee Medical Department, Nashville, 1890; member of the American Medical Association; affiliated with the Anderson Infirmary, where he died Oct. 7, 1947, aged 83, of coronary occlusion.

Louis Arkin, Boston; Harvard Medical School, Boston, 1904; member of the American Medical Association and the New England Otolological and Laryngological Society; served as associate professor of otolaryngology at Tufts College Medical School; affiliated with Beth Israel and Norwood hospitals and the Boston Dispensary; died Oct. 1, 1947, aged 70, of aneurysm of the aorta.

Karl George Avery, Powell, Wyo.; State University of Iowa College of Medicine, Iowa City, 1938; member of the American Medical Association; interned at Salt Lake County General Hospital in Salt Lake City; past president of the Northwestern Wyoming Medical Society; member of the board of directors of the Powell Junior Chamber of Commerce; formerly on the staff of the Worland (Wyo.) Hospital; accidentally drowned recently, aged 32, in Yellowstone Lake in Yellowstone National Park.

Lynn Staley Beals, Captiva, Fla.; Harvard Medical School, Boston, 1904; at one time practiced in Buffalo, where he served on the staff of Lafayette General Hospital; died in the Edward J. Barber Hospital, Lyons, Oct. 1, 1947, aged 70, of cerebral hemorrhage.

Joseph Perley Bodge, South Casco, Maine; Medical School of Maine, Portland, 1899; found dead Oct. 29, 1947, aged 74, of coronary occlusion.

Judson Powell Boulware * Bloomington, Ind.; University of Pennsylvania School of Medicine, Philadelphia, 1916; fellow of the American College of Surgeons; on the staff of Bloomington Hospital; died Oct. 1, 1947, aged 57, of cirrhosis of the liver.

Joseph C. Clawson * Richmond, Ind.; Illinois Medical College, Chicago, 1905; examiner for the county Selective Service Board during World War II; on the staff of Reid Memorial Hospital, where he taught in the school of nursing; died in St. Joseph's Hospital, Tampa, Fla., Oct. 7, 1947, aged 71, of carcinoma.

Howard Dennis Collins, Millbrook, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1893; served during World War I; for many years on the staffs of the City and Knickerbocker hospitals in New York; fellow of the American College of Surgeons; died Oct. 8, 1947, aged 78, of carcinoma.

Clarence Bernard Donges, Camden, N. J.; Jefferson Medical College of Philadelphia, 1891; member of the American Medical Association; died in Cooper Hospital Oct. 6, 1947, aged 78, of coronary thrombosis.

Paul Sarsfield Dougherty, Ojai, Calif.; Tulane University of Louisiana School of Medicine, New Orleans, 1925; at one time on the staff of Good Samaritan Hospital in Los Angeles; died in Fort Worth, Texas, Oct. 11, 1947, aged 48, of arteriosclerotic heart disease.

Frank Sylvester Downey, Sidney, Ohio; University of Cincinnati College of Medicine, 1927; served during World War II; died in the Miami Valley Hospital in Dayton, Oct. 8, 1947, aged 45, of myasthenia gravis.

George John Enders, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1903; served on the department of public health; died in the Hahnemann Hospital Oct. 5, 1947, aged 69, of cerebral anoxia and pulmonary edema.

Israel Feigenoff, Paterson, N. J.; Long Island College Hospital, Brooklyn, 1905; member of the American Medical Association; school physician; on the staff of Barnert Memorial Hospital; died Oct. 4, 1947, aged 69, of coronary thrombosis.

William Anthony Ferraro, Pittsburgh; Marquette University School of Medicine, Milwaukee, 1940; served an internship and residency at the Pittsburgh Hospital; an officer in the medical corps of the U. S. Naval Reserve during World War II; fellow resident at the Memorial Hospital, where he died Oct. 14, 1947, aged 33, of carcinoma of the pancreas.

Joseph Marshall Gallemore, Kansas City, Mo.; Barnes Medical College, St. Louis, 1898 and 1905; died in the General Hospital Oct. 8, 1947, aged 71, of coronary artery disease with myocardial infarction.

Joseph William Gamble @ Albert Lea, Minn.; University of Minnesota Medical School, Minneapolis, 1918; died recently, aged 55.

Arthur E. Genter, Sheboygan, Wis.; Northwestern University Medical School, Chicago, 1894; fellow of the American College of Surgeons; died in Bellin Memorial Hospital in Green Bay, Oct. 5, 1947, aged 77, of cerebral hemorrhage.

Henry A. Hutchinson @ Dixmont, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1878; an Affiliate Fellow of the American Medical Association; member of the American Psychiatric Association; for many years medical superintendent of the Dixmont Hospital, where he died Oct. 5, 1947, aged 91, of chronic myocarditis.

George Delmont Jeffers @ Parkersburg, W. Va.; born in Coolville, Ohio, Aug. 10, 1865; University of Louisville (Ky.) Medical Department, 1889; an Affiliate Fellow of the American Medical Association; past president and formerly member of the council of the West Virginia State Medical Association; served as president of the Academy of Medicine of Parkersburg; president of the medical advisory board for district number 2 during World War I; died in a local hospital Oct. 4, 1947, aged 82, of heart disease.

Albert Joseph Keenan @ Newburgh, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1902; served as clinical professor of otolaryngology at Long Island College Hospital; formerly on the staffs of St. Peter's and St. Mary's hospitals in Brooklyn; died Oct. 3, 1947, aged 69, of bronchopneumonia and sarcoma.

Edwin John Kepler @ Rochester, Minn.; University of Minnesota Medical School, Minneapolis, 1924; associate professor of medicine at the University of Minnesota Graduate School; specialist certified by the American Board of Internal Medicine; member of the Central Society for Clinical Research and the Association for the Study of Internal Secretions; fellow of the American College of Physicians; senior consultant of the section on metabolism of the Mayo Clinic; died Oct. 19, 1947, aged 53, of coronary thrombosis.

Payton Ligon, Henderson, Ky.; Kentucky School of Medicine, Louisville, 1886; member of the American Medical Association; served as county health officer and city and county jail physician; died in Henderson Hospital Oct. 21, 1947, aged 85, of uremia and nephritis.

Charles Sumner Lombard, Redlands, Calif.; Rush Medical College, Chicago, 1881; died recently, aged 94, of senility.

Joseph Douglas McCue, Washington, D. C.; College of Physicians and Surgeons, Boston, 1910; served on the staff of Georgetown Hospital; died in St. Elizabeth Hospital Oct. 20, 1947, aged 66, of purulent bronchitis.

Robert James Northridge, West Upton, Mass.; College of Physicians and Surgeons, Boston, 1912; died Sept. 27, 1947, aged 61, of coronary occlusion.

William Pick @ New York; Deutsche Universität Medizinische Fakultät, Prague, Czechoslovakia, 1919; specialist certified by the American Board of Dermatology and Syphilology; on the staff of the New York Skin and Cancer Hospital; died in the Kew Gardens (N. Y.) Hospital Sept. 8, 1947, aged 55, of myocarditis and pneumonia.

George Ralph Seikel, Akron, Ohio; St. Louis University School of Medicine, 1925; captain in the medical corps, Army of the United States, during World War II; served on the staffs of the Peoples', St. Thomas, City and Children's hospitals and the Edwin Shaw Sanatorium; died in the Veterans Administration Hospital in Cleveland, Sept. 23, 1947, aged 46, of sarcoma and rupture of spleen.

Samuel Z. Shope, Lehighton, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; served as vice president of the Medical Society of the State of Pennsylvania; formerly on the staff of Polyclinic Hospital in Harrisburg; received the honorary degree of doctor of laws from Lebanon Valley College; died in the Allentown (Pa.) Hospital Sept. 18, 1947, aged 75, of uremia and prostatic hypertrophy.

Edgar Kimmel Shumaker @ Los Angeles; Western Pennsylvania Medical College, Pittsburgh, 1902; formerly assistant professor of clinical otology and laryngology at the College of Medical Evangelists; member of the Pacific Coast Otolaryngological Society; died Oct. 3, 1947, aged 68, of subdural hemorrhage.

Furman Robbins Shute, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1899; served during World War I; on the courtesy staff of the Hahnemann Hospital; died Sept. 15, 1947, aged 74, of coronary thrombosis.

Charles Edward Silbernagel, Columbus, Ohio; Cleveland Homeopathic Medical College, 1898; member of the American Medical Association and the American Academy of Ophthalmology and Otolaryngology; affiliated with St. Anthony and Grant hospitals; died Oct. 10, 1947, aged 71, of coronary occlusion.

William Miller Sill, Jamestown, N. Y.; Cornell University Medical College, New York, 1907; member of the American Medical Association; for many years superintendent of public health; on the staff of the Jamestown General Hospital and the Woman's Christian Association Hospital, where he died Sept. 20, 1947, aged 67, of congestive heart failure and arteriosclerosis.

Leo Max Smith, Plymouth, Ind.; Indiana University School of Medicine, Indianapolis, 1944; interned at Methodist Hospital in Gary; died in Parkview Hospital October 9, aged 27, of pneumonia.

Frank H. Southgate @ Fort Thomas, Ky.; Medical College of Ohio, Cincinnati, 1892; served as health officer and as school physician; examiner for the Campbell County Draft Board during World War I; consulting pediatrician at Speer's Memorial Hospital in Dayton; died in Christ Hospital, Cincinnati, Sept. 17, 1947, aged 78, of coronary occlusion and bronchopneumonia.

Lawrence Hefron Stevens, St. Louis; St. Louis University School of Medicine, 1929; member of the American Medical Association; served during World War II; died Sept. 23, 1947, aged 42.

Henry Boardman Stewart, Fountain Inn, S. C.; Atlanta Medical College, 1879; died Sept. 15, 1947, aged 92, of an injury received in a fall.

John Hardin Stewart, Plainview, Texas; Barnes Medical College, St. Louis, 1908; died in Our Saviour's Hospital in Jacksonville, Ill., Sept. 26, 1947, aged 69, of phenobarbital poisoning and chronic myocarditis.

Oliver Morton Stone, Oakland City, Ind.; University of Louisville (Ky.) Medical Department, 1893; died Sept. 19, 1947, aged 80, of endocarditis.

Perry C. Stradley, Glendale, Calif.; American Medical College, St. Louis, 1890; died Sept. 20, 1947, aged 83, of general arteriosclerosis.

Frank Louis Swift @ Dunmore, Pa.; Georgetown University School of Medicine, Washington, D. C., 1915; school physician and director of the Fidelity Deposit and Discount Bank; served on the staffs of St. Joseph's Children's and Maternity Hospital, Scranton State Hospital and Mercy Hospital in Scranton; where he died Sept. 28, 1947, aged 55, of heart disease.

William Martin Sylvis @ Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1907; Jefferson Medical College of Philadelphia, 1908; served as professor of anatomy and associate professor of surgery at the Hahnemann Medical College and Hospital of Philadelphia; fellow of the American College of Surgeons; a medical officer in France during World War I; on the staffs of the Abington (Pa.) Memorial Hospital and the Hahnemann Hospital; died Oct. 1, 1947, aged 65, of coronary thrombosis.

Edward F. Taylor, Maysville, Okla.; University of Tennessee Medical Department, Nashville, 1903; past president of the Garvin County Medical Society; died in Oklahoma City Sept. 17, 1947, aged 74, of arteriosclerosis.

Walter Shaffer Taylor, Alliance, Ohio; Ohio Medical University, Columbus, 1900; served on the staff of Alliance City Hospital; died Sept. 27, 1947, aged 72, of pneumonia and chronic hypertension.

Rudolph S. Vitt, St. Louis; St. Louis University School of Medicine, 1904; also a graduate in pharmacy; past president of the state board of health; member of the American Medical Association; died in Missouri Baptist Hospital Sept. 9, 1947, aged 73, of coronary thrombosis.

John Floyd Wikstrom @ Ogden, Utah; University of Nebraska College of Medicine, Omaha, 1925; president of the Weber County Medical Society; affiliated with Thomas D. Dee Memorial and St. Benedicts hospitals; died Sept. 18, 1947, aged 49, of coronary disease.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Nov. 22, 1947.

Journal for Paraplegics

The Paraplegic Branch of the British Legion announces the publication of a new quarterly journal, the *Cord*, to be devoted to the interests of paraplegics; it will provide information about appliances and medical treatment and how they are to be obtained. General problems of housing and employment will also be discussed. The present issue of the *Cord* contains an interesting short story. A prize of \$8.50 is offered quarterly for the best short story submitted by a paraplegic reader. The annual subscription is only 50 cents. The journal may be ordered from the editor, Paraplegic Branch of the British Legion, Stoke Mandeville Hospital, Aylesbury, Bucks, England.

Great Increase in Blood Transfusions

Among the emergency measures of the war the government maintained a blood transfusion service, mainly for the treatment of civilians injured in attacks from the air. This service proved so useful that it has been continued in peacetime. The official figures as to donors of blood show a great increase in the practice of blood transfusion. During the quarter ending with June, 27,546 new donors joined the National Blood Transfusion Service—approximately twice as many as in the first quarter of the year—and blood was given by 66,557 donors. The estimated panel strength of donors is now about 350,000. To provide for further increase in the demands for blood and plasma and to insure that donors are not asked to give blood oftener than once in every six months, 168,000 new donors are required in England and Wales.

Conference on Mental Health

The National Association for Mental Health will hold a conference in London January 15 and 16. The subjects of discussion and the speakers include the following: "Readaptation to Life and Work of Persons Who Have Suffered from Nervous or Mental Disorder," Drs. G. R. Hargreaves and Donald Stewart. "The Handling of Difficult Children," Mr. E. M. Bartlett, Ph.D., and Miss Clare Britton. "The Responsibilities of Local Authorities in Relation to Mental Health," Drs. Kenneth Soddy and Doris Odum. "Education for Mental Health as a National and International Responsibility," Brig. A. Torrie, M.B., and Dr. J. R. Rees. Inquiries should be addressed to the Conference Secretary, 39 Queen Anne Street, London, W. 1.

Snoring

Snoring is more a nuisance to others than to its subject, and therefore is not regarded as pathologic; hence it has received little attention. At the section of laryngology of the Royal Society of Medicine, Mr. Ian G. Robin read a short paper on snoring. Noisy respiration during sleep may be produced by various structures in the respiratory tract. He limited snoring to sounds made by vibrations of the soft palate and posterior faucial pillars during sleep. It has been shown that the vibrating part in a snore is the thin edge, or velum, of the posterior pillars of the fauces and that if there was a reservoir of air filling the nasopharynx the velum could not vibrate. The vibrating parts are influenced by the relative position of the tongue and soft palate and by the texture of the velum. Minor degrees of nasal obstruction lead to enough mouth breathing to initiate snoring. These conditions include slight deflection of the septum, collapsed alae nasi and moderate nasal congestion. Pathologic changes in the pharynx may make the soft palate and the velum more liable to be in a suitable state for snoring.

The majority of the cases of snoring in children were cured by removal of adenoids and tonsils. Exceptions were cases of

persistent mouth breathing of functional origin and cases of infective or allergic rhinosinuitis. Snoring seldom persisted into adolescence. The child snorer did not progress into the adult type unless there was persistent nasal obstruction. The largest group of sufferers were elderly men and women, the majority of whom had some functional derangement of the glossopharyngeal structures. Lack of tone seemed to be the fundamental cause.

Treatment of Snoring

Of irrational methods of treatment of snoring the chief was amputation of the uvula; this method used to be popular. It seldom gave much relief, though it might modify the depth and pitch of the snore. Of rational methods, the first was removal or prevention of nasal obstruction, thus stopping mouth breathing. In some instances use of decongestive nasal drops before retiring would allow the patient a peaceful night. In others various nasal operations might be necessary. Diphenhydramine ("benadryl") was useful in some cases. The second method was to change the position of the head, thus preventing the tongue from falling back. Many persons snored only when on their backs, and a roll of cotton sewn into the back of the pajamas might be effective. A third method was to alter the position of the tongue and soft palate, and perhaps also the jaws, by breathing, swallowing and phonetic exercises or by orthodontic splints. The object was to train the central nervous system to regain proper neuromuscular control. The splints altered the shape of the mouth, which might prevent the tongue and fauces falling into the critical position. A fourth method was to keep the mouth closed during sleep by wearing an "andresin" splint (which was well tolerated by children but less so by adults) or by the simple expedient of a strip of adhesive plaster across the corner of the mouth. After a short time this was well tolerated by many patients. An adequate nasal airway was, of course, essential.

International Union Against Venereal Disease

The International Union Against Venereal Disease held a general meeting at the Albert Fournier Institute October 20-25, 1947 under the presidency of Dr. William Snow (United States). Among the forty-seven delegates, who represented thirty-eight countries, were: for France, Dr. Cavaillon, general secretary, Professor Gougerot, Dr. Sicard de Plauzolles, Professor Levaditi and Dr. Levy-Bing; for the United States of America, besides the president, Miss Jane Pinney, Dr. J. R. Heller and Dr. L. D. Fullerton; for the Soviet Union, Professors Pavlenko, Pavloff, Agrégés Pachkoff and Katchatourjan; for Great Britain, Mrs. Neville Rolfe, vice president, Dr. R. Forgan, Colonel Harison; for the League of Red Cross Societies, Geneva, Switzerland, Dr. S. Hantcheff; for the World Health Organization, Dr. Guthe, and for the UNESCO, Dr. I. Zhukova. On the agenda were four subjects:

1. Collaboration on a national scale with all practitioners: Dr. Dekeyser (Belgium), Colonel Harison (Great Britain) and Dr. Hermans (Netherlands).
2. Treatment of syphilis by penicillin and arsenicals: reporters, Professors Gougerot and Agrégé Robert Degos (France), Dr. Gerda Kjellberg (Sweden), Dr. Walter Clarke (United States).
3. Social organization of the fight against venereal diseases: reporters, Dr. Gerard (Belgium), Dr. Evans (Norway), Professor Grzybowski (Poland).
4. Sex behaviour and venereal diseases: reporter, Mrs. Neville Rolfe (Great Britain), who, among other things, dwelt on the psychic condition of prostitutes.

The Union considers that the antivenereal campaign can be a complete success only if it is pursued at the same time on the preventive, curative and educational planes and if it asks all governments (a) to put into force a complete sanitary, biologic and moral system of education, especially for the young persons

of both sexes; (b) to organize a complete system of antivenereal dispensaries and to insure the collaboration of practitioners (it being understood that patients will be treated free of charge); (c) to pass regulations permitting the detection of infectious persons both from the national and international points of view and to institute compulsory treatment if patients refuse to undertake it voluntarily, and (d) to perfect the knowledge of venereology among practitioners. In another resolution it was voted to require practitioners to collaborate closely with public health services, with the doctor entitled to fees for his preventive as for his curative action. The Union, considering that important results have been obtained by application of the Bruxelles International Agreement concerning the facilities offered to sailors affected with venereal diseases, begs all governments and the World Health Organization to take urgent measures to effect a new, strict application of this agreement and to consider the possibility of expanding it in an International Antivenereal Convention. Action was taken also to convene an International Sanitary Antivenereal Conference of the benevolent antivenereal organizations in which experts would take part. Attention was focused on the use of sulfonamide drugs by the public, thus creating sulfonamide resistance, and the danger to the public health resulting from the administration of penicillin by the oral route was stressed. The Union decided to create three commissions: (1) for the study of questions concerning the Bruxelles agreement and the fight against venereal diseases among emigrants and displaced persons; (2) for liaison with the World Health Organization, and (3) for the study of the psychobiologic problem of prostitution. The next meeting will be held in 1948.

Cerebral Arteriography

At the Medicosurgical Association in Bologna, Dr. Milletti spoke about differential diagnosis of the various types of endocranial tumors by means of cerebral arteriography.

In 203 cases of cerebral tumors arteriograms made to establish a differential diagnosis of the histologic types revealed data as follows: The arteriograms in 99 of the 203 cases (48.76 per cent) were not of aid in diagnosis of the nature of the tumor. The arteriograms in 104 of the 203 cases (about 51 per cent) were a help in the differential diagnosis.

These arteriograms make it possible to distinguish a benign tumor from a cancerous one. (There was an error of about 4 per cent represented by cases in which the tumor was considered malignant while in reality it was benign.)

It may often be possible to differentiate multiform glioblastoma from sarcoma, especially in those cases of sarcoma in which one can ascertain an outward protrusion of the tumor. It is often impossible to differentiate glioblastoma from oligodendroma: from the arteriographic point of view the behavior of these tumors draws them closer to the cancerous than to the benign tumors.

There is little possibility of differentiating the various forms of benign tumors. Two of 31 cases of astrocytoma (6.45 per cent) demonstrated a peculiar vascularization of the area of the tumor, but these 2 cases were not of a character to allow for differentiation from meningioma. All cases of cholesteatoma were arteriographically negative.

Thus, in practice, the attempts of differential diagnosis by means of arteriography have been given positive results only with regard to two types of endocranial tumors which present themselves most frequently to clinical observation, i. e., the multiform glioblastoma and the meningioma, the former cancerous and the latter benign.

Simultaneous studies of the clinical data which should always be combined with roentgenographic studies by means of contrast medium, and also roentgenographic studies carried out

without contrast medium, may be of additional aid in establishing the differential diagnosis of endocranial tumors.

In conclusion, cerebral arteriography gives the surgeon a diagnostic tool of first importance, and it may be preferred to ventriculography in all cases in which its use is indicated. It may also be used as an important diagnostic adjunct to ventriculography.

Italian Hematologic Association

The Italian Hematologic Association held its eighth National Congress in Pavia. Professor di Guglielmo, director of the Medical Clinic, Naples, acted as president. Among foreign hematologists present were Professor Chevallier of Paris, the Belgian Professor Lambin and the Swiss Professors Moeschlin and Undritz.

The first subject was "Etiopathogenesis and Therapy of Leukemia." The report was divided in four parts. The first part, "Humoral Factors in the Etiopathogenesis of Leukemia," was presented by Drs. Conte Marotta and R. di Guglielmo. Concerning the chemical factors, the report was chiefly on the recent research of the American authors, who have demonstrated substances in the urine of patients with leukemia which are able to provoke the appearance of a histologic leukemic picture in experimental animals. This report was made by Dr. Marotta. There was given a brief outline of the various technics employed by American scientists for the extraction of the leukemogenic principle from the urine, feces and tissues of patients with leukemia.

After that Dr. Guglielmo described the results of American authors in their research either of leukemic patients or on experimental animals. He finally reported his own research, which up to now is not of a degree that affords confirmation of the American reports; considering his limited studies as compared to the scope of those presented by the American authors in research on leukemic patients or on animals, the speaker reserved the right to give a more definite answer when he is able to base conclusions on a larger body of data.

In the second part of the report, "The Results of in Vitro Culture Regarding the Problem of Leukemia" Professor Fieschi presented conclusions derived from his personal research. The third part, "On the Neoplastic Nature of Leukemia," was presented by Professor Storti, who by a careful examination of the cytologic elements, the clinical aspect and experimental studies reached the conclusion that leukemia may be regarded as a neoplastic process of a specific nature.

In the fourth part, "Recent Pathogenic and Therapeutic Discoveries in the Field of Leukemia," Professor Baserga presented statistical data on the incidence of leukemia in relation to seasons, sex, age and family history. He emphasized the prevalence of the disease in men as compared to women, then presented data from his studies which demonstrated the complexity of the problem and the abundance of new points of view. In the field of treatment the speaker developed his concept of the mode of action of various drugs.

A discussion followed. Moeschlin mentioned the importance of treatment with Fowler's arsenical solution, with which in some instances favorable results may be obtained, and with penicillin, particularly when confronted with the risk of oral infection in the acute cases. He also described the favorable results he obtained in some cases with the use of urethane. Lambin disagreed with Baserga by admitting a seasonal influence on the incidence of leukemia; he agreed with him in recognizing the favorable effects of arsenic and penicillin treatment. He prefers urethane treatment to roentgen therapy. Signorelli presented principles, contrary to the concept of the neoplastic nature of leukemia, which were based on the results of his recent studies on the peripheral medullary and splenic cytology. Quattrin considered irreversibility as a differential factor of leukemia from tumors. He did not consider the atypical reports of morphologic changes of the leukemic cell to

be significant; judging from recent studies he admitted the familial character of leukemia.

The second report on "The Genetic Problem of the Rh Factor" was presented by Dr. Morganti, who discussed the Rh factor from the genetic point of view, illustrating his report with graphic records and a large amount of data.

BRAZIL

RIO DE JANEIRO, NOV. 20, 1947.

Study of Blood Transfusions

Drs. Mario P. de Mesquita and Vera Leite Riberio have published the results of an analysis of more than 2,000 blood transfusion records of the blood bank of the Fernandes Figueria Hospital in Rio de Janeiro. During 1945 and 1946 the blood bank furnished blood and plasma for 2,901 transfusions, performed at the hospital or in other institutions, but for only 2,032 of them were complete records available. Of 1,260 blood transfusions with complete records the treatment had been indicated for the following reasons: anemias 749, hemorrhages 190, surgical shock 121, deficiency syndromes 46, dystrophias 53 and other causes 101. The 772 plasma transfusions had been indicated for the following reasons: infectious diseases 106, deficiency syndromes 101, acute dehydration 132, dystrophias 152, cirrhosis of the liver 42, surgical shock 26, malignant tumors 19, hemorrhagic diathesis 20 and other causes 174. Among the 1,260 transfusions 150 reactions occurred (or 11.9 per cent); those 150 cases are divided as follows: chill 63, pyrogen 60, urticaria 14, circulatory shock 9, hemolytic reactions 2 and anomalous reactions 2. In the 772 plasma transfusions only 11 reactions were registered (or 1.4 per cent), divided as follows: pyrogen (chill and fever) 6, urticaria 3 and simple chill 2.

Immunity to Yaws

Since August 1943, the Oswaldo Cruz Institute has had, in the interior of the State of Rio de Janeiro, a rural station for the discovery and treatment of yaws, and several hundred patients have been treated with penicillin. This gave to Dr. F. Nery Guimarães an opportunity to study immunity to yaws, a subject on which few contributions have been made in South America. The study may be summarized as follows:

From the second to the eighth month of the disease there is great resistance to superinfection. Such resistance seems to be independent of the presence of cutaneous lesions, and occurred even in cases with only the initial lesion. From the tenth month to the fourth year of the disease there is a partial immunity which manifests itself in two ways according to the nature of the atypical lesion obtained at the point of inoculation: an attenuated papuloerythematous lesion and a lesion similar to that of the natural infection remained localized at least during the four months that it was observed. This state of partial resistance also seems to be independent of the presence of evident lesions of yaws. The state is not modified by treatment. Patients treated during this stage react to the inoculations in a similar way, although without showing any clinical symptoms and with negative Wassermann reaction.

After the fifth year of the disease superinoculation reveals a greater sensitiveness of the patient. An early papuloerythematous ulcerous lesion, decidedly necrotic and destructive, develops at the point of inoculation; an exacerbation of the patient's lesions occurs at the same time, accompanied by much swelling of the nodes. The lesion obtained in 1 case remained in situ for eighteen months without producing generalized manifestations. Treatment does not modify this state. Patients treated (and improved or totally cured) react in the same way to inoculation during this stage of the disease. Among the 13 patients infected for more than five years ulceronecrotic lesions failed to develop in only 1. He was also the only patient who

never presented gummatous and destructive lesions. On the other hand, 2 patients presenting these lesions but infected for less than three years also did not exhibit ulceronecrotic lesions when superinoculated. These lesions contain treponemes, though only a few.

Since early treatment disturbs the development of immunity, it is advisable from the epidemiologic standpoint to await the end of the secondary period before treating patients in clinics and hospitals, as they may become reinfected. From a prophylactic point of view the primary and secondary lesions must be rapidly eliminated as they are most contagious. In frambesia tropica there is a true immunity and not a simple resistance to superinoculation owing to an active or a latent infection. Thus patients treated and cured clinically and serologically show partial resistance to reinoculation. In this disease immunity takes the form of resistance to superinoculation, or a modification of the initial yaws lesion.

These experiments suggest that the different cutaneous manifestations of yaws are more or less conditioned by the state of immunity of the infected organism. In frambesia tropica the various degrees of immunity are correlated to the age of the infection, but they occur more or less rapidly according to the individual characteristic of the infected organism as well as to the virulence of the treponemes.

Blood Changes in Rats with Benzopyrene Sarcoma

Dr. Carlos A. Salvatore of the Department of Pathology, Paulista Medical School, São Paulo, reported in 1945 his work on the production of large round cell sarcoma in rats after negative transplants of spindle cell sarcomas induced by 1,2-benzopyrene. In some rats the transplant of fragments of the experimental benzopyrene sarcoma produced positive results, but in others the result was negative. Nevertheless, about a year after the absorption of the implanted tumor fragments, the author reported, some of the rats with negative results showed tumors in the lymphatic nodes of the mesentery and of the mediastinum. Those tumors presented a cell picture somewhat similar to that of leukosis, a fact already published by other investigators. Dr. Salvatore found, however, that in his rats the tumor masses were really large round cell sarcomas, as the histologic examination disclosed. Nevertheless, to put aside once more any objection concerning the possibility of the presence of leukemia, Dr. Salvatore decided to repeat his previous experiments, to perform complete hematologic examinations on a new lot of rats under the same conditions. In the first part of the new experiments, now reported, the author attempted a study of the peripheral blood of rats given subcutaneous injections of 1,2-benzopyrene and which presented the induced subcutaneous sarcoma. The blood picture of those rats showed only secondary changes, essentially different from those already reported. Although previously disclosed by others, it is interesting to point out this fact, because it again emphasizes Dr. Salvatore's early work that eliminated leukosis and showed the production of real neoplastic growths. He reports that the intensity of the neutrophilic leukocytosis is correlated with the size of the tumor and therefore with the extension of the central necrosis. He also reports increase of monocytes, oligocytemic anemia and increase of polychromatocytes.

Brief Items

The Brazilian Society of Hygiene held its twelfth annual meeting at Rio de Janeiro October 21-25. The present executive board of the Society includes Drs. Ernani Agricola, J. P. Fontenelle, Carlos Sá, Manoel J. Ferreira and Oswaldo Lopes da Costa.

Dr. J. P. Fontenelle, professor of public health administration at the Curso de Saúde Pública, Instituto Oswaldo Cruz, was elected one of the three vice presidents of the American Public Health Association.

Correspondence

HYDRAULIC LIFT FOR PATIENTS WITH PARTIAL LEG PARALYSIS

To the Editor:—One of the main objectives in muscle reeducation is to afford the patient means of becoming independent of assistance. Capt. Robert Wesselhoeft Jr., U. S. Army Air Corps, who contracted poliomyelitis on the far eastern front, built himself a small stool which he could raise and lower by means of a hand lever operating a screw jack. This was set on large casters which rotated freely in all directions. This enabled him to get off the bed alone onto the stool, which he then lowered by means of the hand lever until his feet had a sufficient purchase on the floor to enable him to propel himself with what remained of his leg muscles. In this way he could transfer himself entirely alone to his wheelchair or any other chair, to the front seat of an automobile and to the toilet seat.

Hydraulic lift for patient with partial paralysis of the legs.

This made him independent of assistance in getting about and thereby greatly helped his morale. Incidentally, it gave his leg muscles purposeful active exercise, thus increasing the strength of those muscles used in propulsion.

Warren E. Collins, Incorporated (555 Huntington Avenue, Boston 15), has modified the original design with a sturdy frame and a hydraulic jack capable of a 34 inch (86 cm.) lift. The stool can be raised by a light to and fro motion of the hand lever and can be lowered at any speed by turning a valve on a separate arm. This device has been in use at Haynes Memorial Hospital for the past few months and has proved to be of distinct value to patients convalescing after poliomyelitis who had sufficient strength in the back, arm and leg muscles. Needless to say, this hydraulic lift serves primarily to make the patient more independent of assistance during that stage of convalescence when the many measures of physical therapy are being employed to restore muscular function. The patient in the illustration is now able to walk by himself with a cane.

CONRAD WESSELHOEFT, M.D., Boston.

SPERM COUNTS, AND STERILITY

To the Editor:—I should like to call your attention to Dr. I. C. Rubin's article published in *THE JOURNAL* (Dec. 28, 1946, page 1047) "Contraception Masking Sterility and Infertility." While most practitioners interested in the field of fertility in men would agree with Dr. Pollack and Dr. E. T. Tyler, who state in their letters to the editor of the *THE JOURNAL*, November 8, page 682, that the normal range of sperms per cubic centimeter of semen is from 60 million to 120 million and that "pregnancies seldom occur when the husband's count is considerably less than 50 million per cubic centimeter, Dr. Rubin, such an authority in fertility and sterility in women, makes in his article the following rather incredible statements: "in an appreciable number of cases the Huhner test showed 10 spermatozoa or less per high power field, despite which pregnancy has taken place," and, "Absence of spermatozoa by the Huhner test, even if found on several occasions, is not always conclusive evidence of male sterility."

If one considers that with each normal ejaculation there are thrown into the female genitals more than 300 million spermatozoa in order that one shall reach the ovum, it is easy to calculate the chances of impregnation when only a few lively ones are ejaculated.

Dr. S. R. Meaker, in his monograph on human sterility, also states that sperm counts in normal cases range from 75 million to 200 million spermatozoa per cubic centimeter of semen.

S. I. MOVITT, M.D., Los Angeles.

TREATMENT OF HYPERTENSION

To the Editor:—The leading editorial in the November 1 issue of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, page 575, mentions the rice diet in the treatment of hypertension and questions the superiority of such a diet over one containing wheat, oats, barley or buckwheat on the basis that there is not adequate scientific evidence to prove its value. This may be the case, but there is evidence that essential hypertension and associated symptoms, such as extrasystoles and paroxysmal tachycardia, can be controlled easily by a somewhat similar diet. This diet was originated for use in the control of allergic symptoms, and it eliminates wheat, milk, egg, potato, pork, tomato, citrus fruits, pineapple and chocolate, the majority of which are basic foods found by many years of experimenting to be the frequent causes of allergic symptoms in a high percentage of patients suffering from allergic diseases.

It was first used in patients with allergic symptoms only, but many patients suffering from headache, perennial vasomotor rhinitis, eczema or gastrointestinal allergy also had what might be called essential hypertension—at least they had maintained blood pressure readings far in excess of normal for their age and weight for years without clinical evidence of cardiac, arterial or renal disease. So many showed such a definite reduction in blood pressure without other therapy that all subsequent patients with essential hypertension were placed on this diet. The results have been so gratifying that this diet seems to me to possess real merit.

The diet is adequate, and a patient cannot be harmed in any way by its use. A few experiments, such as adding each restricted food one at a time for a week, soon indicates which basic foods should be absolutely eliminated if there is a definite increase in the blood pressure. The addition of a food which does not cause an increase in the blood pressure is presumptive evidence of tolerance, and that food is left in the diet. The best possible recommendation for my menu (*J. Missouri M. A.* 38:233-235, July, 1941) is that it works in the treatment of essential hypertension.

LEE PETTIT GAY, M.D.
453 North Taylor Avenue,
St. Louis 8.

Miscellany

PHILOSOPHY OF A MEDICAL SERVICE PLAN

F. L. FEIERABEND, M.D.
Secretary, Surgical Care, Inc.
Kansas City, Mo.

NOTE.—This paper has been condensed from a longer manuscript.—**ED.**
Even until recently many physicians refused to admit the existence of a social problem in medical care. Today, however, most of them recognize and admit that the distribution of medical care is faulty.

Physicians must recognize the moral implication always associated with any social problem. The responsibility for the solution of this social and moral problem must be accepted by the members of the medical profession, and the acceptance must be made by physicians at the local level. Failure to provide the solution is fraught with grave implications, the nature of which has been suggested by two ugly words—regimentation and socialization. Social and moral problems are not solved negatively. The effective solution must be positive. A plan must be developed whereby adequate medical, surgical and hospital care is made available to the people at reasonable cost. Practically, the best plan thus far evolved seems to be one that operates on a budgeted prepayment, nonprofit basis. The technical operation is now well established and is actuarially sound.

Many doctors believe that the American Medical Association should provide the solution of this problem. Such an attitude of local physicians is in keeping with the thinking now exhibited by many citizens. This attitude is best described by the slang expression, "let George do it." Regardless of what the problem may be, many persons say, "What is Congress doing about it? Why don't they pass a law?" Such thinking is false, because in the operation of a democracy it is the responsibility of the citizens that all activity possible must begin at the grass roots level. In recognition of this principle the American Medical Association has not been active in the development of actual operating plans. It has developed Associated Medical Care Plans. This organization will be helpful in promoting, guiding, advising and consulting but will never act in the capacity of actually developing and operating a plan.

To support this thinking, I quote from "Quadragesimo Anno," the great encyclical on the reconstruction of the social order, written in 1931:

It is indeed true, as history clearly proves, that owing to the change in social conditions, much that was formerly done by small bodies can nowadays be accomplished only by a large corporation. Nonetheless, just as it is wrong to withdraw from the individual and to commit to the community at large what private enterprise and industry can accomplish, so too it is an injustice, a grave evil and a disturbance of right order for a large and higher organization to arrogate to itself functions that can be performed efficiently by smaller and lower bodies. This is a fundamental principle of social philosophy, unshaken and unchangeable, and it retains its full truth today. Of its very nature the true aim of all social activity should be to help individual members of the social body, but never to destroy or absorb them.

This is the principle of subsidiarity which is operative in a democracy.

In the United States the people have enjoyed rights and privileges for so long that these are accepted without thought of their source or the obligations incident to the exercise of them. In the American form of government the true source of rights is clearly stated in the Declaration of Independence: "We believe all men to be created equal and endowed by their Creator with certain unalienable rights."

This philosophy is in direct contrast with the philosophy of the materialist Karl Marx, whose "Manifesto" is the Bible of communism. Marx teaches that all rights stem from the state. Great care must be exercised if this insidious social disease known as communism does not become epidemic in the United States. Physicians particularly must recognize their responsibilities if democracy is to survive.

In support of the teachings of the founding fathers, which are clearly stated in the Declaration of Independence, and to prove that their primary motive was sound moral philosophy,

let me quote from the Declaration of Independence written in 1776 and from the writings of Cardinal Bellarmine, written in 1576:

Declaration of Independence, 1776

All men are created equal; they are endowed by their creator with certain unalienable rights.

To secure these rights governments are instituted among men.

Governments are instituted among men, deriving their just powers from the consent of the governed.

Cardinal Bellarmine, 1576

All men are equal, not in wisdom or in grace, but in the essence and nature of mankind.

Political right is from God and necessarily inherent in the nature of man.

It is impossible for men to live together without someone to care for the common good. Men must be governed by someone lest they be willing to perish.

It depends upon the consent of the multitude to constitute over itself a king, consul or other magistrate. This power is indeed from God, but vested in a particular ruler by the council and election of men.

Locke, an Anglo-Saxon, is given credit for being the first to call attention to the idea of "consent" in government. However, Locke received his idea from Suarez, a Spaniard, writing in 1600, and Bellarmine, an Italian, writing in 1576. Both placed emphasis on the consent of the governed and both gave the same philosophic argument to support the idea. Locke deserves great credit for popularizing this thinking.

Observation of the operation of moral law demonstrates that any violation of moral law invokes a penalty that cannot be avoided. These rights must be exercised with great care, and abuse must be avoided unless one is prepared to pay the price. More specifically, these rights include the right to life, bodily integrity, the necessities of existence, the essentials consonant with attaining man's ultimate destiny, the right of association and the right to possess and use property.

The use and exercise of any of these rights creates obligations and responsibilities. Every right and privilege has its commensurate responsibility. Neglect the responsibility and the right will be lost. As a physician, I have rights and privileges. I have the right to expect protection from the state in the exercise of my rights and privileges. This protection, however, may not exceed the protection that is given in the interest of the common good. In the exercise of my rights I must recognize that the implications are dual. In the use of rights or ownership there is a twofold character, individual and social. I must take into account not only my own advantage but also that of the common good. It follows, then, that the exercise of rights must be done in the light as they concern me and as they concern the common good. Since I am a social being, I must recognize that the rights of common good take precedence over the rights of the individual, when the two are in established conflict.

Exercise of my rights and privileges incurs obligations and duties; duties to my fellowmen. As a physician I have been given special training. This training is highly technical and is possessed by few persons. Am I permitted to use this special gift to promote my own selfish desires? As a social being and a component part of a complex society I must recognize that I have a part in the collective task.

Every physician has the obligation to make his special talent available to all the people. No physician by his own efforts could develop all the information he possesses, even though he were a Solomon and lived a thousand years. He must realize that his knowledge was developed by the collective efforts of the multitude that preceded him and that this knowledge may not be exploited. As a doctor, he serves in the capacity of a steward; he must never forget that some day he will be called on to give an accounting of his stewardship. Generally speaking, when physicians are motivated by selfishness, it is the result of living in a materialistic economy and of the almost complete lack of ethical and philosophic teaching in the schools. More and more doctors are now coming to realize that they are social beings and live in a society that is governed by Christian principles. They are beginning to understand that they cannot neglect their duties and retain their privileges. They are perilously close to reaping the just reward of their social sinfulness and neglect. It is their moral duty to make good medical care available to everybody. Right order

dictates that any social duty should be performed by the lower and better qualified group, but it also dictates that the failure of the lower group to recognize and perform its duties makes it mandatory that the higher body provide the answer. By this principle, through their social lethargy and neglect physicians have invited the social planners to invade their domain and usurp their rights. Are the physicians beginning to understand why the serpent of regimentation has reared its ugly head?

I abhor regimentation and communism, and I will oppose the communistic creed with all my energy. I recognize that the regimentation of the medical profession is only the beginning. It is an insidious promise of something for nothing that has its appeal, but the ultimate cost will be liberty—a price one dares not afford. Benjamin Franklin once said, "He who would sacrifice essential liberty for temporary security deserves neither liberty nor security." It is of much greater importance to prevent totalitarianism than to prevent regimentation of the medical profession. Organized medicine has a tremendous responsibility. If physicians permit the regimentation of the medical profession they will have provided the lever to break the seal of democracy and permit entrance of totalitarianism. They will have provided the fertile soil on which the seeds of communism will grow.

If this is to be accomplished, they must reject the teachings of the materialist sociologists and return to the teachings of the moral law. They must reject completely the doctrine of the materialist, which teaches that religion, and morality, is the opium of the people and that man is motivated entirely by instinct. Doctors must avoid this materialistic doctrine or by their acts they will be promoting regimentation. Neglect of social responsibility invites the state to take over with coercion and regimentation.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARD OF MEDICAL EXAMINERS BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in *THE JOURNAL* Dec. 27, page 1167.

NATIONAL BOARD OF MEDICAL EXAMINERS

AMERICAN BOARD OF MEDICAL EXAMINERS: *Parts I & II.* Various centers, Feb. 16-18. *Part III.* Chicago and New York, Jan. 14-16. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Oral.* New York, April 12-15. *Written.* Various Centers, July 16. Final date for filing application is Jan. 16. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 22.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Oral.* Philadelphia, April 2-4. Final date for filing application is January 19, 1948. *Written, Group B.* Various Centers, Feb. 16. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral.* San Francisco, April. Chicago, June. Final date for filing application is Feb. 1. *Written.* Oct. 18. Final date for filing application is June 1. Asst. Sec.-Treas., Dr. W. A. Werrell, 1 West Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral.* Chicago, May or June. Final date for filing application is Feb. 1. Sec., Dr. W. J. German, 310 Cedar St., New Haven, Conn.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Libel and Slander: Physician's Report to Patient Privileged.—The plaintiff sued the defendant physician for damages for slander by virtue of defendant's statement that plaintiff was suffering from a venereal disease. From a judgment in favor of the defendant, the plaintiff appealed to the district court of appeal, fourth district, California.

The plaintiff called at the office of the defendant physician on August 20 for treatment for injuries received in a fall down an embankment. Her condition was such that defendant deemed it necessary to give her a thorough physical examination, including tests for venereal disease. A sample of urine and a smear were taken by defendant and sent to a reputable laboratory in San Diego, Calif., for examination. Two days later he received a report from the laboratory to the effect that the microscopic examinations of both specimens indicated the existence of the venereal disease, which defendant had suspected as a result of the physical examination. The day before this, in response to a telephone message, the defendant had made a professional call on the plaintiff at her home and had made an appointment for her to call at his office the following morning, which appointment she did not keep. On receipt of the report from the laboratory, and because of the plaintiff's failure to keep the appointment, the defendant caused a letter, dated August 23, to be sent to her which contained the following:

Your laboratory report arrived this morning. It shows you are suffering from a venereal disease.

Under the law, we are compelled to report this to the health authorities, and to advise you against working in any establishment handling foods.

We are anxious to assist you, and we will hold up this report for twenty-four hours to give you a chance to step in and discuss your problem.

As the plaintiff did not appear at defendant's office he had one of his nurses telephone her at the drugstore where she worked. Plaintiff was not at the drugstore but her mother was there taking her place and, according to the nurse, she merely requested the mother to urge the plaintiff to call at defendant's office. The mother, however, testified that the nurse told her that the plaintiff was suffering from a venereal disease. The next day the plaintiff's landlady telephoned to defendant's office and asked that the defendant stop bothering the plaintiff, as the phone calls created commotion at the drugstore. The secretary who took this message understood it to be a request for the defendant to make a house call on plaintiff and so informed the defendant. Defendant therefore called on the plaintiff about twenty minutes later, and the conversation occurring at that meeting forms the basis of this action.

Present in the room at the time were the plaintiff and her landlady. Plaintiff's mother and a neighbor were, unbeknownst to the defendant, in an adjoining room. The landlady answered the door and told the defendant that she had called him. He wanted to know why. She said, "You should know the reason why, because of the letter that Mrs. Shoemaker has received from you." He asked her, "What letter?" and she said, "Do you mean to say that a letter like that would come out of your office without your knowledge?" He said, "If you are talking about any letter, you will have to take that up with my office nurse"; and then he asked her, "What letter?" and if he could see it. She said the letter was in a physician's hands and would be in a lawyer's hands, so he turned to the plaintiff and asked why she was suing. She replied, "Who said I was suing?" Then he shook his finger in the plaintiff's face and said, "Young lady, you are suffering from a severe case of gonorrhea." The plaintiff said, "Dr. Friedberg, I don't see how you can say that when I have negative reports from a laboratory saying that I don't have it." He answered, "I too have laboratory reports from a reliable laboratory that you have a positive smear and are suffering from a severe case of gonorrhea, and if you don't do something about it and come to my office I intend to make drastic charges against you." He turned and walked out the door.

The plaintiff testified that she received the defendant's letter on the morning of August 24; that a neighbor, Mrs. Burgomaster, was helping care for her and received the letter from the postman; that she told Mrs. Burgomaster the contents of the letter and that perhaps she read it; that she disclosed the contents of the letter to her mother and to the landlady prior to August 25. She then consulted another physician, who sent her to another laboratory in San Diego. A slide smear was made and examined microscopically and a culture was made, both with negative results. The defendant testified that he did not know that the plaintiff's mother or the neighbor were in the adjoining room and within hearing distance of the conversation. The plaintiff, however, knew of the presence of both of them but made no effort to check or adjourn the conversation concerning the letter and its contents, which conversation was opened and seemingly invited by the landlady. The statements of defendant conveyed no new knowledge to either the landlady or the plaintiff's mother, however, as the plaintiff had already told them of the letter and its contents. We must conclude, said the court, that it was news to the neighbor although the plaintiff testified in a deposition that she had told the neighbor of the laboratory report before August 25. The plaintiff contends that the foregoing constituted sufficient publication of the slander to be actionable.

We must first examine the question of qualified privilege, said the court. One privileged communication is defined by subdivision 3 of section 47 of the Civil Code, as follows: "In a communication, without malice, to a person interested therein, (1) by one who is also interested, or (2) by one who stands in such relation to the person interested as to afford a reasonable ground for supposing the motive for the communication innocent, or (3) who is requested by the person interested to give the information." Section 48 of the same code, in effect in August 1945, provided: "In the cases provided for in subdivisions three, four, and five, of the preceding section, malice is not inferred from the communication or publication." The plaintiff and defendant occupied the relation of physician and patient. It was the duty of the defendant, as her physician, to treat plaintiff and to inform her of the ills from which he believed she was suffering. The letter written by him was addressed to plaintiff and truthfully conveyed to her the information given him by a reputable laboratory, which information he believed to be true. That the subject matter of this letter concerned a subject in which both parties were interested cannot be questioned. Therefore it was privileged as to plaintiff. Further, the writing of this letter to the plaintiff was not a publication of its contents under the slander laws of this state. Its original publication was by plaintiff herself when she disclosed its contents to her mother, her landlady and the neighbor. As defendant had no part in this publication he cannot be held responsible for it. What is the situation, however, with regard to the neighbor who was in the dinette at the time of the conversation? Mrs. Rice was a neighbor of the plaintiff and a tenant of the plaintiff's landlady, living in one of two houses on the same lot, and she walked in the back door at about the same time as the defendant entered the front door of the house. The plaintiff, the landlady or the plaintiff's mother had not invited her to come and did not know that she intended to do so, but all of them knew of her arrival. The defendant was positive that he did not know of her presence. It appears that the neighbor was merely a casual bystander who overheard the remarks of the defendant without any connivance on his part. The mere fact, said the court, that third persons not legally interested in the communication are accidentally present and hear it will not alone take the case out of the privilege if it were unavoidable or happened in the usual course of business affairs.

We therefore conclude, said the court, that as the statements of the defendant were qualifiedly privileged as far as three of the hearers were concerned and were overheard by the fourth, who was merely a casual bystander for whose presence the defendant was in no manner responsible, plaintiff cannot recover without proof of actual or express malice on the part of the defendant. Under these circumstances the burden of proving such malice rests on the plaintiff.

A physician is required by rules of the board of health to report a case of venereal disease within twenty-four hours of its discovery; if the infected patient takes and continues treatment, only the initials need be placed on the report, otherwise the name must be given. There is nothing in the record to support a finding of actual or express malice on the part of defendant, said the court. He actually received a report from a reputable, established laboratory that the plaintiff was suffering from a venereal disease. He believed, relied and acted on this report. The fact that this report from the laboratory was a mistake, if such be true, cannot affect the question of actual malice if the defendant believed it to be true and was actually acting on that belief and was proceeding without malice within the provisions of the venereal disease law. The defendant testified that his requests that the plaintiff consult him in his office were made with the idea of inducing the plaintiff to take treatments so as to save her the embarrassment of having her name rather than her initials reported to the board of health. There is nothing in the record contradicting this testimony, and the inferences from the entire record support it. Therefore the conclusion is clear that instead of being actuated by any malice against the plaintiff, defendant was endeavoring to protect her as much as possible from the effects of any publicity concerning the disease from which he believed she was suffering.

As the statements made on August 25 were qualifiedly privileged and as there was no proof of actual or express malice, plaintiff failed to meet the burden of proof resting on her. Accordingly the judgment in favor of the defendant physician was affirmed.—*Shoemaker v. Friedberg*, 183 P. (2d) 318 (Calif., 1947).

Workmen's Compensation Acts: Refusal of Employee to Submit to Operation for Removal of Coccyx.—The plaintiff filed a claim for compensation for injuries sustained as the result of an industrial accident and was granted a maximum award for total disability. From this award, the defendant appealed to the court of appeal of Louisiana.

After discussing the facts surrounding the occurrence of the accident, the court of appeal concluded that the plaintiff was entitled to compensation for total disability unless, as the defendant contended, her refusal to submit to a coccygectomy suspended her right of recovery. The medical testimony, said the court, as to the character of this operation is almost unanimous and is to the effect that it is a simple operation unattended by danger to life. It is for the most part likened to an appendectomy. In a prior Louisiana case, however, the Supreme Court said: "If we were to consider that the tendered operation was to be regarded in the nature, as to the seriousness thereof, of a tonsillectomy, an appendectomy or an abdominal operation for the removal of a tumor, it certainly could not in the light of the jurisprudence of this state be considered such an operation that the employee's refusal to undergo it would be unreasonable or arbitrary." The plaintiff, said the court, continues to suffer pain in the region of her pelvis, though she complains particularly of her coccyx, and while she has definitely refused to submit to the removal of her coccyx on the ground that she is afraid and will not do so as long as she can bear the pain, she seems to be justified in her refusal. While practically all the medical experts agree that the operation is a simple one, nevertheless the defendant's physician is of the opinion that: "She could have the coccyx removed and this would probably cure the pain in this region, but this is not a simple operation and should be done only by a bone surgeon or by a surgeon who has had some experience in doing this kind of work." This physician also said: ". . . unless you know your anatomy . . . and operate properly, . . . the damage to the soft tissue around, particularly the nerve filaments, will result in a painful condition even after the operation." Under these circumstances the court of appeal held that the plaintiff's refusal to submit to an operation for the removal of her coccyx was not unreasonable. Accordingly the judgment in favor of the plaintiff was affirmed.—*Jacobson v. Maryland Casualty Co.*, 30 So. (2d) 887 (La., 1947).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Aneurysm of Pulmonary Artery.—According to Deterling and Clagett true aneurysm of the pulmonary arterial trunk or its major branches is rare in that only 8 cases were discovered in 109,571 necropsies. The authors analyze 36 cases of aneurysm of the pulmonary artery proved by necropsy and collected from the literature. The addition of this group to the 111 cases proved at necropsy and reported by Boyd and McGavack in 1939 brings the total number of authentic cases to 147. The authors stress the advisability of omitting cases in which only the clinical diagnosis has been made. Although syphilis was a definite factor in more than a third of the cases, congenital cardiovascular anomalies also play a major role. A patent ductus arteriosus is present in more than 20 per cent of the cases. Other less common causes are subacute bacterial endarteritis, atheroma and trauma. The early symptoms are dyspnea, cough and pain in the thorax. Cyanosis and edema usually are later manifestations, often dependent on cardiac failure or congenital anomalies. The heart, especially the right ventricle, frequently is enlarged. Right axis deviation is common. Most significant is the roentgenoscopic finding of a discrete pulsatile hilar mass, separate from the aortic shadow. The case described by the authors concerned a man, aged 37. The clinical diagnosis was confirmed by necropsy. There were a patent ductus arteriosus, atheroma of the right pulmonary artery and bilateral pulmonary arteriosclerosis as well as a history of trauma. Surgical cure by ligation of the right pulmonary artery and pneumonectomy was prevented by the extent of the aneurysm and the atheromatous calcification of the vessel.

Heart Size in Neurocirculatory Asthenia.—Carloti and his associates say that past reports of investigation of heart size in neurocirculatory asthenia or effort syndrome emphasized the apparently small size of the heart shadows. They measured the cardiac diameters and areas of 67 patients with neurocirculatory asthenia and compared them with similar measurements of 50 healthy subjects in the same age group, between 20 and 30 years of age, and also with the measurements of young men who have been ill with tuberculosis. They found that when heart areas and heart diameters were adjusted for body surface area of each subject there were no statistically significant differences between those with neurocirculatory asthenia and normal controls. Heart sizes in healthy controls and in those with acute and chronic neurocirculatory asthenia or tuberculosis were not very different when adjustments were made for body size.

"Pitressin" Test of Coronary Insufficiency.—Ruskin points out that in view of the powerful vasoconstrictor effects of "pitressin," particularly on the coronary arteries, the use of this agent suggested itself as a test of latent coronary insufficiency,

to differentiate true angina pectoris from other conditions associated with chest pain. Patients with recent myocardial infarction or congestive heart failure were excluded, but patients considered to have angina pectoris and those whose symptoms were regarded as nonanginal in type were given slowly increasing doses of "pitressin." For a subject of 70 Kg. in weight satisfactory dosages were found to be 2 cc. (40 pressor units) intramuscularly or 0.75 cc. intravenously, injected in about sixty seconds. The criteria of a positive test have been taken to be change of a positive T wave in leads 1, 2 or 4 to a flat, diphasic or negative T wave, or ST segment deviations totalling 3 mm. or more in leads 1, 2, 3 and 4 F. Close parallelism was noted in the results of the "pitressin" and Master exercise tests in both the positive and negative cases. Of 12 patients with clinically typical angina pectoris, the "pitressin" test was positive in 8. The Master test was positive in 5 of the 8 patients and negative in 3. The test, confirmed by the Master test in the former group, was negative in 10 patients with atypical precordial pain and 5 normal controls. Positive tests confirm the clinical suggestion of coronary pain; negative tests do not exclude it. The side effects of "pitressin" render its general use as a test for latent coronary insufficiency inadvisable. In the hands of experienced investigators it may be useful in the evaluation and management of coronary sclerosis and for experimental purposes. The results of the use of "pitressin" attest both coronary spasm and relative myocardial ischemia as theoretic bases for clinical anginal pain.

Extract of Hog Stomach in Ulcerative Colitis.—Ehrlich asserts that with few exceptions, such as amebic and bacillary dysentery and tuberculous enterocolitis, ulcerative colitis is a nonspecific disease. Proteolytic enzymes are present in the colon and the rectum. Gastrointestinal hypermotility, whether it be neurogenic, psychogenic or gastrogenic, increases the delivery of proteolytic enzymes into the colon, thus predisposing the colonic mucosa to autolysis. It is presumed that the colon normally contains an antiproteolytic or protective substance to inhibit dissolution of the mucosa. This antiproteolytic substance seems to be particularly deficient in the descending colon and rectum under the mentioned circumstances, thus upsetting the proteolytic-antiproteolytic enzymatic balance, predisposing the individual to mucosal autolysis. Desiccated extract of hog stomach appears to contain this antiproteolytic substance. Fifteen cases of idiopathic ulcerative colitis are reported in which extract of hog stomach was administered. An average dose of 40 Gm. was given in divided doses before meals. In the protracted and fulminating cases, the initial dose was always 60 Gm. a day: it was gradually reduced as amelioration of symptoms and endoscopic improvement resulted. At least 6 ounces (177 cc.) of liquid should be taken with or immediately following administration of the extract. The dosage was not reduced until adequate resolution was evident by endoscopic visualization. In each case a sigmoidoscopy was performed at weekly intervals during the active phase, then once a month. A maintenance dose of 10 Gm. of extract three times daily was continued for from one to four months. Edema, inflammation, spasm and ulceration subsided under the influence of the hog stomach extract. Four patients required sulfonamide therapy for secondary infections.

- Anticoagulant Therapy with Heparin. G. Murray.—p. 468.

Hyperparathyroidism.—Rogers and Keating review the published cases of primary hypertrophy and hyperplasia of the parathyroid glands and summarize the observations in 4 patients seen at the Mayo Clinic. They stress that primary hyperplasia of the parathyroid glands is a distinct pathologic entity and that it must be differentiated from parathyroid adenoma composed of clear cells, from metastatic renal cell carcinoma to the thyroid and from secondary parathyroid hyperplasia. They discuss the difference between hypertrophy and hyperplasia and present evidence for the assumption that both are present but that hyperplasia predominates. They review the clinical implications of primary hyperplasia. In the majority of the reported cases of primary hyperplasia the patients have had obvious hyperparathyroidism. Bergstrand was the first to suggest that primary parathyroid hyperplasia is the counterpart in the parathyroids of exophthalmic goiter in the thyroid. This concept appears to be justified. The authors believe that the histologic picture of primary hyperplasia always indicates a primary excess of parathyroid hormone.

Benign Pneumoconiosis Due to Metal Fumes and Dusts.—Sander thinks that the term pneumoconiosis requires redefinition because it is widely misunderstood. Its generic meaning is "dust added to the lungs," without any implication of what reaction may have resulted from the dust. Only two dusts are known to cause significant fibrotic reactions in the lungs: free silica and asbestos. Because silicosis and asbestosis are the best known pneumoconioses, the terms fibrosis and pneumoconiosis have become almost synonymous. The benign pneumoconioses are those resulting from inert deposits of dust in the lungs, which are not the cause of fibrosis or disability. Siderosis is one of these. The author adds to the list of occupations which may be producers of siderosis that of metal cutting with the oxyacetylene flame. He reports 3 cases which have the following diagnostic points in common: (1) discrete and rather sharply defined rounded shadows of more or less uniform size and equal distribution in both lungs; (2) no tendency to confluence of the shadows, and (3) hilus shadows always smaller than would be expected with silicosis of this degree. Gross black pigmentation at necropsy has been erroneously diagnosed as

anthracotic, when ferrocyanide stain would have revealed iron. Gross round lesions also have been incorrectly diagnosed as silicotic without use of the connective tissue stains to determine whether they were true fibrotic nodules. These differential procedures are recommended for all nodular or stippled roentgen shadows. Finally, more careful analysis of past exposures to dust is recommended whenever a roentgenogram shows nodular shadows.

- *Early Postoperative Ambulation. E. A. Balcer.—p. 472.

Early Postoperative Ambulation.—Balcer reviews experiences with early ambulation in 144 patients who underwent varied abdominal operations. Patients are allowed out of bed the morning of the first postoperative day except when definite contraindications are present, such as shock, severe abdominal distention, cardiac decompensation and second side thoracolumbar sympathectomies and demonstrable vasomotor instability in the upright position. The method consists of having the patient turn on his side and of winding the bed to a sitting or semisitting position. The feet are then assisted over the edge of the bed by the attendant, and with the help of the nurse the patient sits on the side of the bed. Then comes standing for a few seconds and taking deep inspirations. This usually results in a productive cough, the mechanics being the emptying of the accumulated bronchial secretions. The patient then walks to a chair and sits down. The return to bed is accomplished in the same manner. The procedure is repeated in the afternoon. On each successive day the activity is increased. Analysis of the complications developing in 8 patients reveals that none were caused by the early ambulation. The improved general appearance, the absence of abdominal distention, the reduced necessity of catheterization and gastric decompression and the infrequent need for oxygen therapy are some of the benefits of early rising.

Endolymphatic Hydrops (Ménière's Disease).—Williams states that much of the confusion with regard to Ménière's syndrome has been dissipated by the discovery of the true pathologic picture in authenticated cases of this disorder. In such

cases gross dilatation of the endolymphatic system, affecting chiefly the scala media (ductus cochlearis BNA) and the sacule and utricle, is present. Minor degenerative changes are found in the organ of Corti and at times in the stria vascularis. Inflammatory changes have been conspicuously absent. Atkinson's theory has little if any clinical or laboratory evidence to support it. Measures have proved effective which were directed toward correcting the electrolyte balance in the tissue fluids, toward controlling fluid metabolism or toward stimulating the autonomic nervous system and producing vigorous vasodilation. At the Mayo Clinic atropine or epinephrine has been found helpful in controlling the acute attack. As regards surgical treatment, there is a choice between a major neurosurgical procedure entailing craniotomy and a minor surgical procedure requiring no more than thirty minutes for its performance. The author feels that in the United States as in England labyrinthotomy is destined to replace intracranial division.

Herniated Intervertebral Disk.—Peyton and Simmons analyze 90 cases in which operation was performed for herniation of a disk. The disk was considered pathologic only in cases in which a loose fragment of disk tissue was observed lying free in the spinal canal or in which there were definite bulging and spontaneous protrusion of nuclear material when the annulus fibrosus was opened. Eighty pathologic and 10 normal disks were exposed at surgical operation. The relief obtained was essentially the same with simple removal of the lesion as with removal and spinal fusion. The results were satisfactory in the group of 80 cases in which a definitely pathologic disk was removed. Seventy-two patients were followed, and only 3 had continued pain or disability, of unknown origin. The results were not good in the 10 cases in which exploration was considered to have revealed no lesion of the disk. This indicates that simple removal of the lesion of the disk is a satisfactory operation and that improvement in results is likely to be realized through better selection of cases for operation rather than through the introduction of new operative procedures.

Radical Mastectomy.—McGraw attempted to discover what eventually happens to women who have undergone the Halsted radical mastectomy and have survived five years or longer. He has follow-up information on all but 6 of 412 patients. A recent check reveals that 177, or 43 per cent, of the women survived the operation five years or more. Comparison of the results for those of the 177 patients who had early postoperative roentgen therapy with the results for those who did not is inconclusive as to any clearcut beneficial influence of such treatment on the prognosis. The author does not wish to imply that early postoperative roentgen therapy is either harmful or without possible value. The patients to whom such treatment was given were not selected with sufficient consistency and impartiality to warrant conclusions. The proportion of women with axillary involvement who received roentgen therapy was considerably larger than that of the women who were free from such metastases. The author has become strengthened in the conviction that a thoroughly radical operation is at present the only procedure that gives patients a good chance of long survival. Such

an operation should be undertaken whenever it can be performed with technical adequacy unless coexisting metastases are so advanced or widespread and the patient's expectancy of life is clearly so short as to make operative intervention futile.

Section of Vagus Nerves.—Crandell and his associates studied a group of patients undergoing section of the vagus nerves for peptic ulceration. Preoperative and postoperative tests have demonstrated the following facts: 1. The secretion of gastric acid in response to alcohol administered intravenously or intragastrically appears to be diminished after section of the vagus nerve. 2. Section of the vagus nerve does not change the electroencephalographic pattern of patients with peptic ulcer. 3. Nitrogen balance studies did not indicate any impairment of utilization and absorption of protein as a result of supradiaphragmatic section of the vagus nerve. 4. Diminished gastric motility has been found clinically and roentgenographically. Certain unpleasant symptoms have been attributed to the resultant dilated stomach.

Television in Surgical Operations.—Trimble and Reese point out that the customary method of demonstrating surgical operating technique to students and to visiting doctors has proved unsatisfactory for two reasons. The observers cannot see the operating field properly; these observers bring contamination into the operating room. To overcome these difficulties the authors conceived the idea of employing television. On Feb. 27, 1947, television of surgical operations was used for the first time at the Johns Hopkins Hospital. Five operations were transmitted to ten television receivers in four different classrooms. Through a loud speaker system the surgeon described each operation step by step as he performed it. Before operations were commenced the camera recording the operating field was clamped to the overhead operating light 4½ feet (137 cm.) above the operating table and was accurately focused. So sharp was the image that when a dollar bill was placed on the operating table the serial numbers could be clearly read on the projection screens. A 135 mm. focal length lens gave a field of view of 8½ by 11½ inches (21.6 by 29.2 cm.) at this distance. Each step in the operation was clearly recorded by television. The second television camera was installed in the gallery of the operating room to show a general view of the activity in the operating room. Pictures which were taken by this second camera were at times flashed on the projection screens, alternating with the first camera, which was recording a close-up view of the operative field only.

Starvation Edema, Serum Protein and Forced Feeding in Anorexia Nervosa.—Berkman, Weir and Kepler point out that during and after World War I it was observed that starvation often was followed by edema, and in about half of the subjects the concentration of the serum proteins was decreased. It also was observed that under apparently identical circumstances normal values for serum proteins might be obtained and that definitely subnormal values were not necessarily associated with edema. Possibly because the observations first mentioned were more in keeping with Starling's theory of formation of edema, emphasis was placed on the importance of the serum proteins in maintaining a dynamic equilibrium between the intravascular and interstitial fluids. During and following World War II emphasis was placed on the absence of correlation between starvation edema and the concentration of serum proteins. Starling's concepts have been scrutinized and sometimes discredited. The authors were interested in the manner in which patients who were emaciated as a result of anorexia nervosa have gained weight. Thirty-one patients with anorexia nervosa were studied at the Mayo Clinic with particular attention to the weight curve during dietary treatment, the occurrence of edema and its relation to the weight curve and the relation of the edema to the concentration of serum protein. No pitting edema was observed at any time in 15 patients, while in 12 patients edema was present on admission. Four patients acquired edema during treatment, and in 6 instances preexistent edema was increased following treatment. Among the patients who recovered from emaciation and may never have exhibited edema, the character of the weight curve suggested that a sequence of events occurred which was identical in character with those which occurred in patients who did exhibit edema. In the treatment of anorexia nervosa three phases can often be seen in the weight curve. In the first phase edema may occur or increase if it has been present. In the second phase edema may persist or slowly decrease while the patient gains flesh. The weight of water lost is approximately equal to the weight of the flesh gained. In the third phase the disturbance in water balance has been corrected, waterlogging has been overcome and a progressive gain in weight occurs. The weight curve may be misleading in evaluating the actual storage of flesh. In severe cases of untreated anorexia nervosa values for the serum proteins more often than not were within the normal range. In about a third of the cases values lower than normal were encountered. The level of the serum protein usually could not be correlated with

the presence or absence of edema. With treatment, the concentration of serum protein may decrease temporarily, possibly because of hemodilution.

Sclerosing Therapy of Esophageal Varices.—Four years have elapsed since Patterson and Rouse first employed the injection of a sclerosing solution through the esophagoscope in the treatment of esophageal varices. They present data on the effect of this measure in 24 patients, who had as their chief presenting complaint recurring massive hematemesis. The authors stress the decreased incidence of hemorrhage after injection therapy, as compared with the incidence of hemorrhage before this treatment.

Carcinoma of Islets of Langerhans.—Gordon and Olivetti review 20 cases of carcinoma of the islets of Langerhans from the literature and describe 2 new cases. They emphasize that carcinoma of the islets of Langerhans is a rapidly growing tumor which occurs more commonly in males, is more frequent in middle age, may or may not produce hypoglycemia, arises oftenest in the tail of the pancreas and metastasizes quickly and widely to neighboring and distant structures, but oftenest to the liver and to nearby lymph nodes. The usual histologic criteria for malignancy are not applicable to an islet cell tumor. It is only the presence of metastases that reveals its malignant nature.

Effect of Impurities on Penicillin Therapy.—Hobby and her associates say that impure penicillin was found to be three to five times more effective than crystalline penicillin G in protecting mice against experimentally produced hemolytic streptococcus infections. The same difference in activity has been demonstrated against pneumococcal infections in mice. The factor in impure penicillin which enhances the chemotherapeutic activity of crystalline penicillin G is present in the original penicillin fermentation liquor and may be demonstrated during the extraction of penicillin in those fractions in which penicillin G is recovered. The chemotherapeutic activity of crystalline penicillin G may be enhanced by dissimilar substances not specific for impure penicillin. Furthermore, crystalline penicillin K may enhance the activity of crystalline penicillin G. The effect of penicillin G plus K is greater than would be anticipated from the total number of units present. The chemotherapeutic activity of penicillin X, dihydro-F, and at times K may also be enhanced by penicillin impurities.

Sensitization to Streptomycin in Nurses.—Strauss and Warring previously gave histories of 4 nurses in whom contact dermatitis developed from streptomycin. In this communication they present detailed descriptions of these patients and add 2 more cases of sensitization to the same drug. These 6 cases occurred in a group of 12 nurses who came in contact with streptomycin in the course of administering it to patients and rinsing out the syringes. In the first 4 nurses the eruption appeared at intervals varying from one month to three and a half months after the first exposure to the drug. All exhibited positive reactions to patch tests to streptomycin, and in all the eruption disappeared when exposure to the drug was avoided. The possibility that streptomycin in the concentration used is a primary irritant must be dismissed, because it failed to produce a reaction not only in 4 persons who had never been exposed to streptomycin but also in 6 who had had varying degrees of exposure to the agent. The 2 nurses who, although they never had any eruption, exhibited sensitivity to streptomycin on patch testing demonstrate more clearly the potentialities of this drug as a sensitizer.

Meningitis Due to *Alcaligenes Faecalis*.—Terry and his associates say that although *Alcaligenes faecalis* is generally considered to be saprophytic and nonpathogenic, it seems that this organism can produce disease. A review of the literature reveals that *A. faecalis* has been associated with a variety of clinical conditions such as rheumatic polyarthritis, hepatitis and appendicitis. The organism has been cultured from gallstones and renal calculi. It has been considered the pathogenic agent in certain types of infant summer diarrhea and the cause of a few cases of adult enterocolitis. There are only 4 cases in the literature in which *A. faecalis* was responsible for meningitis. The case reported herein, that of a seaman aged 42, apparently represents the fifth case of meningitis due to *A. faecalis* to be described. Despite high in vitro resistance of the organism to streptomycin and sulfadiazine individually, the patient recovered under treatment with these two agents combined; synergistic activity may have been present. Preceding infection with, or port of entry for, *A. faecalis* could not be demonstrated. Agglutinins for the organism could not be demonstrated in the blood after recovery.

Powdered Blood Plasma and Eggwhite for Gastrointestinal Disorders.—While assigned to a prisoner of war camp, de Rohan Barondes observed that a considerable percentage of the confinees, and troops stationed nearby, complained of various gastrointestinal disorders, gastritis, enteritis, hyperchlorhydria, ulcerous states, diarrhea and the like. Due to insufficiency of proper agents for alkalitherapy at the time, powdered blood plasma was used. Desiccated blood plasma, when given orally, exerted beneficial effects on such gastrointestinal disorders as hyperchlorhydria, gastritis, enteritis, ulcerous and malignant processes and diarrheas. Blood plasma acts as a buffer for gastric acidity, exerts a soothing influence on inflamed and diseased tissues, is a fibrinogenic agent through its plasma globulin content, aids tissue regeneration and possesses antitoxic and antibiotic properties. In addition, it aids in the capacity to fabricate antibodies and increases resistance to infection. The dried plasma is well tolerated when mixed with palatable cool mixtures. Hot fluids are not used as excipients because coagulation of the plasma then readily occurs with loss in its therapeutic properties. An excellent agent for the incorporation of the plasma is apple powder, which is likewise a valuable agent in treatment of gastrointestinal disorders. Blood plasma is superior to the amino acids and protein hydrolysates in quickly combating hypoproteinemia, maintaining nitrogen balance and restoring the electrolyte equilibrium. This would be especially so in the presence of a severely damaged liver. Eggwhite, either fresh or prepared by the high vacuum cold process similar to that used in preparing blood plasma, is effective in ameliorating the symptoms of various gastrointestinal disorders. The desiccated product can be prescribed in enteric-coated capsules or mixed with cool fluids.

- Sarcoidosis.—p. 555.

Streptomycin Therapy in Bacterial Infection.—Kane and Foley report the results obtained with streptomycin in 52 cases which included infections of the urinary tract, meningitis and epiglottitis due to *Hemophilus influenzae*, bronchiectasis, nonspecific urethritis and 1 case of septicemia caused by *Pseudomonas aeruginosa*. After review of the effects obtained in 38 cases of pyelonephritis and 2 of cystitis due to gram-negative bacilli, the authors say that cure was effected in 30 and improvement in another 4; the remaining 6 were not improved. Cure resulted when the infection was due to a susceptible organism, despite moderate renal damage and the presence of small nonobstructing renal calculi. Patients infected with organisms with in vitro resistance greater than the levels that could be obtained in the urine failed to respond. The acquisition of resistance by the infecting organism was not responsible for the failures. An appreciable increase in resistance was observed in only 1 case. Two of 3 cases of nonspecific urethritis in which only pleuropneumonia-like organisms were isolated responded to streptomycin therapy. Two cases of meningitic influenza also responded to streptomycin. Recovery in 2 cases

of epiglottitis due to *H. influenzae* seemed to be hastened by streptomycin therapy. The favorable outcome in 1 case of septicemia due to *P. aeruginosa* was undoubtedly the result of the prompt use of streptomycin. Of 3 cases of bronchiectasis in which *Escherichia coli* was the predominating organism in the sputum, only 1 showed clinical improvement after combined penicillin and streptomycin aerosol. One patient with pulmonary abscess thought to be due to *H. influenzae* seemed to improve on combined penicillin and streptomycin aerosol. Minor toxic reactions were observed in 15 per cent of cases.

Chlorophyll for Dermatoses.—Langley and Morgan resorted to water soluble chlorophyll when other measures had failed to relieve the subjective symptoms and objective manifestations of dermatoses of varied type. The majority of the 40 cases had proved resistant to all previous treatment. One of the most gratifying results of application of water soluble chlorophyll was its ability to relieve itching and burning. This alleviation was welcomed by the patient, who in many instances became comfortable for the first time in weeks or months. Thirty-six of the 40 patients also obtained objective improvement, whereas 4 did not improve. Thirty-two of the 36 were clinically cured. The authors are unable to explain the mode of action of chlorophyll but suggest that it may provide some factor which inflamed tissues need for healing.

Arteriotomy in Arteritis Obliterans.—Leriche treated 144 aged men and women who had arteritis obliterans by arteriotomy. The superficial femoral artery was involved in 90 patients, the deep femoral artery in 22, the external iliac artery in 17, the aorta in 2, the popliteal artery in 15, the posterior tibial artery in 7 and the subclavian, axillary and humeral arteries in 11 patients. Five cases in men between the ages of 64 and 78 years are reported in detail. Permanent results were obtained in about 45 to 50 per cent of the cases. Secondary amputation was required in 27 cases. Failures were

due to the rapid occurrence of dry gangrene. Vasomotor disturbances hastened the appearance of complete ischemia, which had remained below the threshold before the surgical intervention. In spite of these failures and 9 postoperative deaths, arteriotomy may be considered as a benign intervention which suppresses the vasoconstrictive pathologic arterioarterial reflexes and which produces changes in the peripheral circulatory system. It checks the progress of the thrombosis which is the cause of continuous aggravation. Arteriography may be of considerable aid in the decision favoring arteriotomy or amputation. Arteriotomy may be performed under local anesthesia. It should be extensive and 15 to 25 cm. of the superficial femoral artery should be removed. Lumbar ganglionectomy was combined with arteriotomy in 9 of the author's cases. This combined treatment may increase the chance of success provided that the general condition does not contraindicate the intervention.

"Benadryl" for the Common Cold.—Brewster used diphenhydramine hydrochloride ("benadryl hydrochloride" N. N. R.) experimentally in the treatment of about 100 cases of the common cold. It has been found to completely abort 10 per cent of such cases and to shorten the course and afford subjective relief to the patient in 95 per cent of all cases. This is due to its inhibiting effect on the serous discharge from the mucous membrane of the upper part of the respiratory tract and its soporific effect. It inhibits the cough reflex, especially in children, probably because it eliminates postnasal drip. It aborts fever blisters.

*Acute Interstitial Polymyositis Treated with Penicillin. I. Friedmann and F. Por.—p. 494.

Penicillin in Acute Interstitial Polymyositis.—Friedmann and Por report the case of a woman, aged 42, in whom a sudden chill was followed by pain and swelling of all the limbs. When she was hospitalized ten days later all her limbs were greatly enlarged. The muscles appeared hypertrophied and were tender, and some of them were transformed into large lumps, especially the right sternocleidomastoid, both biceps, both brachioradialis and the upper parts of the abdominal recti. The evening temperature was 102 F. The patient remembered that she had eaten pork, and, although the number of eosinophils was not high enough for trichinosis and there were no swellings of the face and eyelids, a tentative diagnosis of trichinosis was made. A biopsy specimen was taken from the right sternocleidomastoid. The normal muscle tissue was largely replaced by a cellular inflammatory infiltrate consisting mainly of leukocytes, many of them eosinophils. The widely separated muscle fibers had partly lost their striation and had undergone waxy degeneration. Trichinae were not found. The histologic diagnosis was acute interstitial eosinophilic polymyositis. On the twenty-first day of illness treatment with penicillin was instituted, and after six days the temperature dropped to normal and remained so. The swellings were diminishing and the general condition showed great improvement. After receiving 1,500,000 units of penicillin the woman felt so well that she was discharged. She has been well and healthy since.

Sudden Death From Injection of Mercurial Diuretic.—Oettlé says that sudden death may follow directly on the intravenous injection of an organic mercurial and reports a case to illustrate this. Presumably death was due to ventricular fibrillation. Treatment should consist of intracardiac epinephrine and sodium thiosulfate. To prevent such sequelae mercurial diuretics should never be given by the intravenous route. The addition of magnesium sulfate to the solution for injection promises to lower its toxicity considerably.

- *Iron-Staining Erythrocytic Inclusions with Special Reference to Acquired Hemolytic Anemia. A. J. S. McFadzean and L. J. Davis.—p. 237.

Erythrocytic Inclusions in Hemolytic Anemia.—Bodies resembling those described by Pappenheimer in 1945 were studied by McFadzean and Davis in a variety of hematologic conditions. These bodies occur within erythrocytes and their hemoglobinated precursors, both in the peripheral blood and in the bone marrow. They give a positive iron reaction and stain with Leishman, methyl blue, pyronine and a number of other stains but fail to do so with specific nuclear stains, namely, hematoxylin and methyl green. Seven cases of acquired idio-

pathic hemolytic anemia were described with special reference to the incidence of inclusion bodies. Before splenectomy, which was performed in 6 of the cases, these bodies were numerous in the sternal marrow but relatively scanty in the peripheral blood. Shortly after splenectomy the incidence in the bone marrow was unchanged but the number of red cells containing inclusion bodies in the peripheral blood underwent a dramatic increase, which was commensurate with the rise in the total red cell count. It is suggested that the red cells containing the inclusion bodies may normally be removed by the spleen and that the mechanism responsible for the inclusion bodies may constitute a major etiologic factor in acquired hemolytic anemia. Similar inclusion bodies have been found in the peripheral blood and sternal marrow in a variety of hematologic disorders, but their incidence never approached the high figures seen in acquired hemolytic anemia. The inclusion bodies differ from the granules of siderocytes but appear to be related to the basophilic stippling of lead poisoning. The nature of the inclusion bodies is unknown, but it is suggested that they develop as the result of interference with hemoglobin anabolism.

Excretion of Drugs in Human Milk.—Sapeika reports that many of the observations described by Reed in a review published in 1908 still hold good. The fact that it is practically never necessary to remove the child from the breast when the mother is receiving drug therapy is borne out by the rarity of cases of untoward reactions reported in the literature. Another important point that still holds is that it is rarely if ever desirable to treat a child with drugs given to the mother. Reed concluded that alcohol, opium, chloroform, ether, thyroid and lead are to be used with care, and that atropine, antipyrine, phenacetin, chloralhydrate, arsenic, bismuth, mercury or copper compounds, castor oil, senna, quinine, bromides, iodides, salicylic acid and copaiba pass into the milk in small quantities. In his review of reports that have appeared since 1908, Sapeika says that unusually large quantities of alcohol or chloroform have been known to influence the nursing. Excretion of barbiturate into breast milk has been demonstrated, but the amount is generally too small to affect the infant. It is known that bromides may cause cutaneous eruptions in infants. With regard to morphine the author states that alkaloid has not been found in the milk of an addict taking 20 grains (1.29 Gm.) of morphine sulfate daily, while in a normal woman given 16 mg. of this drug, a trace may have been present in the milk seven and one-half hours later. A decrease in milk secretion has been noted as the result of excessive smoking by the mother, and nicotine has been detected in breast milk. Nicotine intoxication in factories or from excessive smoking may affect the mother and also the child. Although minute quantities of conjugated phenolphthalein may be found in breast milk, no obvious effect on the bowel movements occurred in the infants of mothers taking phenolphthalein. The active constituent of senna, cascara or rhubarb may produce purgation in the suckling. Sulfonamide compounds have been observed to reach higher levels in the milk than in the blood, but the amount ingested by the infant is too small to be dangerous.

Intra-Thoracic Lipomata. J. Smart and V. C. Thompson.—p. 163.

Coarctation of Aorta.—Crafoord and his associates thought that in patients with congenital isthmus stenosis, who already had a satisfactorily functioning collateral arterial system, it would be possible to keep the aorta closed at a point immediately peripheral to the left subclavian artery for longer than twenty-seven minutes without endangering the patient. They describe the surgical technic used by Crafoord to remove the stenotic part of the aorta and to restore continuity by end to end anastomosis. Fifteen patients have been subjected to this operation, with good results in 11. Two patients died as the result of the operation, and in 2 others the coarctation could not be removed. The authors stress the importance of oscillographic studies in coarctation. The roentgenologic changes which are pathognomonic are (1) widening of the left subclavian artery, which is visible as (a) an S-curved outline of the left border of the superior mediastinum, (b) an impression on the esophagus, (c) an indentation of the left border of the posterior mediastinum and (d) a modification of the impression of the aortic arch on the esophagus; (2) discrepancy between the increased pulsations in the left subclavian artery and the decreased pulsations in the adjacent part of the descending aorta. Inconstant changes are widening of the costal sulci, shortening of the aorta, widening of the innominate artery and enlargement of the left auricle.

Fatal Staphylococcal Poisoning of Infant in Maternal Mastitis.—A woman aged 23 was hospitalized two months after confinement on account of mastitis. The breast had become painful, red and tender two weeks previously, but she had continued to nurse her baby until two days before she came to the hospital. Incision of the breast exposed a cavity filled with pus which yielded *Staphylococcus aureus*. The infant was found to be thin, exhausted and with poor turgor and tone. Although the infant's temperature was normal on admission, it suddenly became febrile and there were several green, loose and mucous stools. Enteritis was diagnosed and sulfaguanidine was given, but the infant died. At necropsy cultures of the intestinal contents yielded mainly *Staph. aureus*. An examination of nine strains of staphylococci obtained from cases of puerperal mastitis showed that six of them were enterotoxic. In most cases of mastitis pain prevents breast-feeding, but in a few cases it is continued. Selberg thinks that when an infant is feeble, when its nutritional state is poor and when its resistance is low, breast feeding should be discouraged at the slightest sign of mastitis.

Genital Tuberculosis.—Clemetsen reports the case of a woman, aged 29, who requested treatment for sterility. A laparotomy was performed and disclosed considerable changes around the internal genitalia, with dense adhesions and thickening of both tubes. On the right side the tube and the ovary formed a solid inflammatory tumor, which was removed. The left ovary was normal and was left intact. On histologic examination the removed tube presented tuberculosis. About eight months after the operation there developed a tuberculous ulcer on the penis of the husband of this woman. On the assumption that the uterine endometrium of the wife contained tubercle bacilli, the menstrual blood was examined and yielded tubercle bacilli on Löwenstein's medium.

Fatal Agranulocytic Syndrome Due to Administration of Marenin in Therapy of Undulant Fever. C. Pirastu.—p. 346.

Diet in Pathogenesis and Therapy of Liver Disease.—The author gives the histories of 80 patients with acute or subacute disease of the liver due to intravenous injections of arsenicals or other drugs. In the acute cases there were jaundice, fever, ascites, general intoxication and enlargement of the liver and the spleen; in some cases, pleurisy and progressive loss of weight. The feces were acholic in some acute cases. Treatment with liver extracts, blood transfusions and intravenous administration of dextrose solution with patients on hypoproteic diet failed. Complete recovery without recurrence was obtained in all cases on a diet rich in protein.

*Eosinophilic Granuloma of Bone and Its Relation to Hand-Schüller-Christian's Disease and to Abt-Siwe-Letterer's Disease. J. Bartels.—p. 2578.

Eosinophilic Granuloma of Bone.—Bartels describes the histories of 2 boys, aged 5 and 6 years, respectively, with solitary eosinophilic granuloma of the cranium. Both patients were operated on and one also received roentgen treatment. The author discusses eosinophilic granuloma of bone, Schüller-Christian's disease and Abt-Siwe-Letterer's disease and the possible relationship of these three entities. In a boy, aged 2 years, whose case is presented in detail, all three entities were present. The author concludes that his observations confirm the idea of some investigators that the three disorders are variants of a single disease entity, Abt-Siwe-Letterer's disease being the severest of the three.

- *Clinical Factors Disposing to Postoperative Thrombosis in Gynecologic Patients. Elisabet Weltman and P. Wetterdal.—p. 1669.

Postoperative Thrombosis in Gynecologic Patients.—Weltman and Wetterdal's study of 142 cases of thrombosis after gynecologic operation and 480 cases without thrombosis after operation shows a greater tendency to thrombosis after operative intervention for myoma, prolapse and salpingitis and in patients with fever and increased blood sedimentation rates. Patients with cardiac weakness and with a history of thrombosis are especially liable to thrombosis after operation. Increased predisposition to thrombosis because of adiposity,

anemia and high blood pressure or age was not demonstrable, nor was thrombosis found to be more likely to occur after several pregnancies or after longer confinement to bed before operation.

*Diabetes Mellitus Caused by Trauma to the Trunk. P. Louyot, Girault, S. Hadot and Arnoux.—p. 610.

*Experimental Study of Therapeutic Activity of Streptomycin in Tuberculosis. C. Levaditi and A. Vaisman.—p. 611.

Traumatic Diabetes Mellitus.—Louyot and his co-workers report 1 case of traumatic diabetes mellitus in a factory worker aged 48. In the course of his work the man stumbled over a cable and sustained a violent dorsolumbar and abdominal trauma. One month later diabetes mellitus was manifested by loss in weight, generalized edema and a neurologic syndrome characterized by the abolition of the cutaneous and tendon reflexes. Insulin treatment was instituted, combined with prolonged administration of vitamin B₁ and a course of trans-pancreatic short waves. Six months after the accident the polydipsia, polyuria and edema disappeared suddenly, while the carbohydrate intolerance still persisted. The neurologic symptoms subsided slowly. Several months before the accident the workman had submitted to a thorough check-up and was observed to be normal in every regard; the violent trauma and the rapid occurrence of diabetes supported the diagnosis of traumatic diabetes. The disappearance of the polyneuritic syndrome although the diabetes still persisted suggests that the first was not of diabetic origin but that both were sequels of the trauma. While traumatic diabetes is in general grave, resulting in death from pancreatic lesions in two-thirds of the cases, recovery may occur in exceptional cases and is then associated with carbohydrate intolerance. The stabilization at this rate requires several months. From the medicolegal point of view, traumatic diabetes, because of its important social and therapeutic consequences, entitles one to liberal compensation.

Streptomycin in Tuberculosis.—Levaditi and Vaisman inoculated mice with 1 mg. of Koch's bacillus (*Mycobacterium tuberculosis*). In the first series of experiments 24 mice received 1,000 units of streptomycin daily and 17 mice served as controls. In this series treatment was started simultaneously with the inoculation. In the second series 80 mice were given first 1,000 units and then 2,000 units of streptomycin, with 37 mice serving as controls. In this series treatment of 40 mice was started simultaneously with the inoculation and another 40 mice were inoculated twelve days before treatment was started. These experiments demonstrated that streptomycin is one of the most effective agents for the treatment of experimental tuberculosis in mice. It does not completely destroy the tubercle bacilli but limits itself to checking their multiplication. In the battle between the microbes which are in the stage of bacteriostasis and partial bacteriolysis, and the defense power of the organism, the latter prevails over the former. The germs ingested by the phagocytes undergo involutional alterations. At the same time the tissue lesions present a cicatrization capable of opposing the invasion by the bacteria. There is no radical sterilization; in spite of the prolonged survival of the mice, their lungs continue to be virulent to guinea pigs. Discontinuation of the treatment is often followed by grave recurrences. The identity of the conclusions drawn from these experimental results and those reached from clinical observations in men is striking.

*Madrid Symptomatic Complex: Paresthesia of Legs and Burning Feet. M. Peraita.—p. 225.

Madrid Symptomatic Complex.—In 1941 Peraita wrote his book "Avitaminosis y sistema nervioso," in which he described a syndrome of paresthesia of the legs and burning feet in 66 patients. The syndrome was a result of the lack of proper food during the civil war in Spain (1936-1939). The

etiology was unknown, but at the present time and through similar reports in the literature it is known that the disease is caused by lack of the vitamin B₂ complex and controllable by its administration.

Revista de Psiquiatría, Santiago

11:51-126 (No. 2) 1946. Partial Index

*Rh Factor Blood Incompatibility and Mental Diseases. M. F. Beca.—p. 51.

Rh Factor Blood Incompatibility.—According to Beca, 9 of 11 patients with encephalopathies due to erythroblastosis with kernicterus reported in the literature showed the Vogt syndrome, whereas 2 did not exhibit neurologic symptoms. Instances of mental defect in a child due to incompatibility of the Rh factor in his and his mother's blood, without neurologic symptoms, have also been reported. Isoimmunization of the mother to the Rh blood factor plays an important role in the production of oligophrenia with or without the neurologic sequels of kernicterus. Rh blood incompatibility is frequently the causal factor of oligophrenia of unknown origin. There are certain cases of well verified incompatibility (the mother with Rh negative blood and the child with Rh positive blood) in which erythroblastosis with acute jaundice is followed by recovery of the patient without mental and neurologic symptoms. The fact is explained by a lack of lability on the part of the neurons to degenerate. Nervous constitutional lability accounts for erythroblastic degeneration, whereas diffuse cortical lesions and subarachnoid hemorrhages are the result of nervous lesions which produce oligophrenia. Erythroblastic lesions predominate in the gray nuclei at the base of the brain, but they diffuse also in the forms of cortical atrophy and subarachnoid hemorrhages.

*Hormone Effects of Vernix Caseosa. L. Lajos and F. Szontágh.—p. 81.

*Thiamin Content of Human Milk. J. Sós.—p. 111.

Hormone Effects of Vernix Caseosa.—Lajos and Szontágh say that the development of the newborn is more favorable if the vernix caseosa is not immediately removed. The similarity of effects of vernix caseosa and of estrogenic hormone treatment suggested that the vernix may contain hormones. To ascertain this, the authors made animal experiments which revealed that the subcutaneous injection of vernix caseosa is followed in infantile ovariectomized rats by full estrus. Similar results could be obtained by inunction of vernix into the skin. Vernix caseosa is absorbed readily by the skin. Vernix caseosa tested on the ovaries of infantile mice lacked gonadotropic effect; the uteri showed changes identical with those produced by large doses of estrogen. It is concluded that vernix caseosa contains a fairly large amount of estrogen.

Thiamin Content of Human Milk.—Sós reports that at his institute assays have been made on the vitamin B₁ (thiamin) content of the milk of 102 mothers, 38 of whom had inadequate protein and fat intake. The average thiamin content was 11 micrograms per hundred cubic centimeters, but the surprising fact was that the milk of the undernourished group had a higher vitamin B₁ content than that of the well nourished group. The higher vitamin B₁ content of the poorly nourished group was not explained by their smaller amount of milk, and although the vitamin B₁ content is generally higher during the first three months after delivery than later, the concentration does not closely depend on the period that has elapsed since childbirth. The time of day at which the assay sample is withdrawn and the specific gravity of the milk likewise seem to be of no great importance as regards the thiamin content. Studies on infants up to 6 months of age suggest that the thiamin content of human milk does not completely cover the requirements of infants and that other sources are needed.

Book Notices

Skin Manifestations of Internal Disorders (Dermadromes). By Kurt Wiener, M.D., Dermatologist, Mount Sinai Hospital, Milwaukee, Wis. Cloth. Price, \$12.50. Pp. 690, with 392 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1947.

A great deal of effort has gone into the writing of this book, for there are some 3,000 references cited, many from journals not easily accessible. The result is an excellent, informative book, skillfully written to preserve the proper balance between the systemic symptoms and the dermadromes, a name coined by the author and intended to signify the cutaneous part of a syndrome. This is the first current book of any length on the subject (another just released by Behrman is in brief handbook form), and it is said to be the first one in the English language since 1906.

The book has many praiseworthy features. The descriptions of the various syndromes are concise and clearly written; the references appear in full title on the bottom of each page; both established facts and controversial matters are presented; the illustrations are numerous and well selected. The forty-three chapters cover a wide field. The subject matter includes practical and experimental phases of metastatic infections, "id" reactions and a large group of systemic infections including the exanthems. There are chapters devoted to the mycoses, virus diseases, rickettsial diseases and diseases of the circulation, kidneys, endocrines, metabolism, pregnancy and blood-forming organs and many rare and tropical diseases.

The author obviously intended to cover the field in a complete manner, and he did a commendable job. Unfortunately, histoplasmosis does not appear among the mycoses or in the index, and there is no mention made of diphtheritic ulcers. However, the book is unusual and merits high recommendation. It contains an amazing amount of information and should be useful to both practitioners and dermatologists.

Le diabète et sa pathogénie. Par L. Ambard, avec la collaboration de Mlle. S. Trautmann et de M. D. Kuhlmann. Paper. Price, 240 francs. Pp. 162, with 17 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6^e, 1946.

Professor Ambard's monograph illustrates the famine of current scientific literature in war-torn countries.

It would be desirable if this eminent author could write a second edition based on the new work in diabetes. He could appreciate and thoroughly evaluate (1) the contributions of Cori; (2) the part played by hexokinase; (3) experimental production of diabetes by the creation of hyperglycemia announced by Dohan and Lukens; (4) contributions of Stadie and Stetten to fat metabolism and to the knowledge of the conversion of carbohydrates to fat; (5) use of isotopes in intermediate carbohydrate metabolism; (6) disappearance of diabetic coma and the importance of truly large amounts of insulin in the first few hours of treatment; (7) replacement of coma as a cause of death by arteriosclerosis in its various forms, and (8) discovery of alloxan diabetes.

This author would be the first to build on these developments. All would welcome a second edition in which he could review the recent work done throughout the world.

Endocrinology of Neoplastic Diseases: A Symposium by Eighteen Authors. Editors: Gray H. Twombly, M.D., and George T. Pack, M.D. Cloth. Price, \$11. Pp. 392, with illustrations. Oxford University Press, 114 Fifth Ave., New York 11, 1947.

Evidence that hormones affect the abnormal as well as the normal metabolism of the cell necessitates a comprehensive review of the relationship of hormones to neoplastic disease. Drs. Twombly and Pack have enlisted the aid of eighteen experts in the preparation of this monograph. Material on which this monograph is based first appeared in *Surgery*, July and August 1944. These articles have since been thoroughly revised and brought up to date as of August 1946.

The book is divided into three parts: The first part deals with experimental tumors induced by steroid hormones; particular attention is paid to tumors developing in the genital tract. Discussion of evidence regarding effects of continued use of

female sex hormones on subsequent development of neoplastic disease in human beings is of interest. The conclusion is reached that although under special conditions in animals it is possible to increase the incidence of such tumors it has not been demonstrated that these results are applicable to human beings.

The second part of the book deals with effects of tumors of endocrine glands. This part is well illustrated and contains digests of the original case histories from which the classical descriptions of these diseases were taken. Particular attention is paid to pituitary and adrenal tumors.

The third part of the book deals with absorbing and little understood effects of hormones on neoplastic diseases. Special attention is focused on effects of estrogens on prostatic tumors and of estrogens and androgens on cancer of the breast, particularly the bony metastases.

The book has not been arranged in the order discussed but in accordance with the glands involved. This may be a useful arrangement for the endocrinologist, but the value of this monograph extends beyond the field of endocrinology. For those interested in problems of cellular growth in neoplastic diseases and those who seek general information on this fascinating subject, another arrangement of the material might be more logical and informative.

L'Infezione brucellare nell'uomo. Dal Prof. Dott. Saverio Signorelli, Libero docente e assistente di patologia speciale medica e metodologia clinica nella R. Università di Napoli, Napoli. Prefazione del Prof. Giovanni di Guglielmo. Paper. Price, 300 lire. Pp. 327, with 43 illustrations. Casa Editrice Libreria Vittorio Idelson, Via E. De Marinis, 19, Naples, 1941.

"L'Infezione Brucellare nell' Uomo," the author explains, is a complete treatise on brucellosis. The book is the result of years of experience with excellent clinical material. The author offers the manual to those interested in brucellosis and discusses its relationship to each of them.

This monograph is timely because, as Huddleson has recently observed, in America in spite of radical measures to suppress bovine brucellosis the infection is still prevalent.

The manual is a complete treatise dealing with the various aspects of brucellosis—historical, etiologic, pathologic, serologic, immunologic and clinical. An English translation of this manual would be an invaluable aid to the veterinarian, physician and others who feel the need for further information concerning brucellosis.

Veterinary Bacteriology. By Ival Arthur Merchant, D.V.M., Ph.D., C.P.H., Professor of Veterinary Bacteriology and Head of the Department of Veterinary Hygiene, Division of Veterinary Medicine, Iowa State College, Ames. Third edition. Cloth. Price, \$7. Pp. 683, with 137 illustrations. The Iowa State College Press, Ames, Iowa, 1946.

Veterinary bacteriology is related so closely to medical bacteriology that the two groups overlap. For this reason the author has included such human pathogens as the typhoid bacillus, the gonococcus and other forms. The book has been brought up to date, and a chapter on antibiotics has been added. Chapters on protozoa and milk analysis have been omitted, because those subjects are otherwise included in the curriculum at Iowa State College.

The material is presented clearly, illustrations are good, and each chapter has adequate references. It is a good book on bacteriology.

Medical Care and Costs in Relation to Family Income: A Statistical Source Book. Selected and compiled by Helen Hollingsworth, Margaret C. Klem and Anna Mae Baney. Federal Security Agency, Social Security Administration, Bureau of Research and Statistics, Bureau Memorandum No. 51. Second edition. Paper. Price, \$1.25. Pp. 349. Washington, D. C.: Supt. of Doc., Government Printing Office, 1947.

This statistical material was selected and compiled to further the cause espoused by the Social Security Administration in its official recommendations: compulsory national health insurance. Users of this memorandum may check the source neatly printed at the bottom of each table and then consult the description of the source in the early pages of the memorandum; thus one may form an opinion of the value of the data from the value of the source. The memorandum is an invaluable source of statistical material for researchers in medical economics and allied fields.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TUBERCULOSIS

To the Editor:—Approximately what percentage of patients with minimal tuberculosis have a positive sputum at some time during the course of their disease? What is the approximate percentage in the moderately advanced and far advanced groups? After examining the tuberculous patient, what is the best method for cleansing the hands and articles used in the examination? Does washing in green soap and water solution kill the bacilli and is sponging with alcohol a sure method? Do you think face masks are much protection, particularly the loose woven types? How much higher percentage of physicians working in sanatoriums develop tuberculosis than those in other types of practice.

Clyde Alley Jr., M.D., Portsmouth, Va.

ANSWER.—Unless tubercle bacilli can be recovered through the sputum or gastric washings, it is impossible to determine that a demonstrable pulmonary lesion, whether minimal or advanced, is tuberculous. If the patient reacts to tuberculin, the lesion may be tuberculous. However, nontuberculous pulmonary disease is as likely to develop in the lungs of tuberculin reactors as in nonreactors. Stiehm found tubercle bacilli in the gastric washings of about 70 per cent of persons who had minimal lesions that might be due to tuberculosis. A definite diagnosis could not be made in the remaining 30 per cent, although it was presumed that they represented tuberculous processes because they were in young people who reacted to tuberculin, and the x-ray shadows persisted over at least a period of months.

Most persons with minimal chronic tuberculous lesions have no cough or expectoration for weeks, or even months, in the early development of the disease. It is only those which progress so as to result in the destruction of tissues in whom such symptoms and positive sputum appear. In some of the others the lesions may completely resolve; those in still others fibrose and always remain minimal in extent. Therefore, when a minimal lesion is present on first examination, the physician has first to determine whether it is tuberculous and, if so, whether it has been well controlled by nature or is progressive.

Nearly all persons in whom the disease progresses to moderately or far advanced stages have tubercle bacilli in the sputum or gastric washings at some time. Even these lesions may become so well controlled by the natural defense mechanism that they do not eliminate tubercle bacilli that can be found in the gastric washings or sputum. Failure to find tubercle bacilli in such cases does not mean that the lesions are nontuberculous if the patient reacts to tuberculin. It has been found that the sputum may contain a thousand or more (estimated as high as a hundred thousand) tubercle bacilli per cubic centimeter without having them found by the usual methods of sputum examination. Therefore one should always resort to cultures, and preferably animal inoculations, before stating that tubercle bacilli are not present in the sputum or gastric washings.

Careful washing of the hands and various articles in green soap and water solution and sponging with alcohol does not constitute a sure method of killing tubercle bacilli. However, this is probably adequate if carefully done, as most of the bacilli are removed from the surface of the skin. The time during which soap and alcohol remain on the skin is not adequate to destroy the organism. In absolute alcohol tubercle bacilli die in five minutes, and 5 per cent phenol (carbolic acid) requires the same time to kill them. One per cent tricresol or 2 per cent saponated solution of cresol are effective germicides, but from several minutes to an hour is required to destroy tubercle bacilli.

While the usual face mask may not afford absolute protection, there can be no doubt that when properly used it definitely reduces the number of tubercle bacilli which enter the air and are deposited on the bedding and other objects in the vicinity of the patient. In some places where serious effort is made to protect personnel against tubercle bacilli, masks are worn both by the patient and by persons who examine, treat and give other care. There is considerable need for an impervious mask which protects the entire head and neck.

The exact percentage is not known, but definitely more physicians who work regularly in sanatoriums and on tuberculosis services in general hospitals have tuberculosis than those in other types of practice. This has been true since the early days of the sanatorium in Europe. A good many physicians go into

sanatorium work after they develop tuberculosis, while others contract the disease in the sanatorium. Alarming numbers of students of medicine who take training in sanatoriums and on tuberculosis services of general hospitals without rigid contagious disease technic develop primary tuberculosis and therefore become reactors to tuberculin. Among such physicians are those who later develop clinical lesions, some of whom may return to the sanatorium as staff members. Exacerbations are not uncommon among sanatorium physicians. These may be due in part to exogenous reinfections.

TESTS FOR SENSITIVITY TO PENICILLIN

To the Editor:—Are there any reliable tests for determining hypersensitivity to penicillin?

F. Harold Krauss, M.D., Philadelphia.

ANSWER.—With reference to diagnostic tests, reactions to penicillin may be divided into three types:

1. Contact dermatitis to penicillin in those who engage in its manufacture and administration and in those who receive topical applications of penicillin preparations. In such types of allergy to penicillin the patch test with the antibiotic will show an eczematoid reaction and is of diagnostic value (Friedlaender, S.; Watrous, R. M., and Feinberg, S. M.: *Arch. Dermat. & Syph.* 54:517 [Nov.] 1946).

2. In some of the immediate reactions to injection or oral administration, consisting of urticaria, a scratch or intradermal test may give a positive reaction to a solution of penicillin. Usually, however, such reaction is negative; even when present it must be carefully controlled by tests on nonallergic persons, since penicillin in high concentrations gives false positive intradermal reactions.

3. The commonest type of penicillin reaction, which occurs several days after the administration of the drug, has the characteristics of serum sickness and usually consists of urticarial rashes, arthralgia and fever. Such reactions are not associated with positive skin tests. It should be pointed out further that the positive skin test obtained with extracts of the penicillium fungus in patients who have hay fever or asthma from the inhalation of mold spores is not accompanied by a positive skin test to penicillin (Feinberg, S. M.: *J. Allergy* 15:271, 1944).

Observations thus far indicate that such patients are no more likely to have reactions to penicillin develop than those who are not mold sensitive.

CHRONIC ALCOHOLISM

To the Editor:—A patient of mine requests that I do something radical to cure him of chronic alcoholism. He claims he heard some radio program wherein an operation "for draining the fluid from the brain" was offered as a cure for this condition. I had him check this and he was told that the treatment consisted of a lumbar puncture. What results are claimed for such treatment, and at what intervals is the puncture repeated?

M.D., New York.

ANSWER.—H. Goldsmith (*Amer. J. Psychiat.* 10:255, 1930) recommended spinal puncture for the treatment of acute alcoholic episodes. He expressed the belief that this treatment may be of value in preventing recurrences of the episodes. E. S. Cowles (*Med. J. & Rec.* 133:417 and 472, 1931) stated his belief that cerebrospinal edema is responsible for the symptoms of chronic alcoholism and that repeated spinal punctures remove the edema. When the edema has thus been corrected the craving for alcohol disappears. The evidence presented seems too meager for acceptance at this time. Furthermore, the data presented lose much weight when one considers Cowles's assertion that alcohol may be present in the spinal fluid of chronic addicts for six weeks after the ingestion of spirits. After weighing the evidence with regard to spinal puncture in the treatment of chronic alcoholism, W. L. Voegtlin and F. Lemere (*Quart. J. Stud. on Alcohol* 2:717, 1942) concluded: "Spinal drainage and other efforts to reduce cerebral edema have produced inconclusive and inconstant results."

POLIOMYELITIS

To the Editor:—Can you tell me whether the virus of poliomyelitis has been isolated or found in the urine of patients suffering from this disease?

M. D. Horneda, M.D., El Paso, Texas.

ANSWER.—Efforts have been made to recover the virus of poliomyelitis from urine of patients suffering from this disease without success. Whereas a transient paralysis of the bladder which sometimes is present early in this disease would indicate that the virus may affect the urinary system this is probably a mediated effect through nerves controlling the bladder rather than a direct effect of the virus on the bladder parenchyma itself.

SYMPTOMS FOLLOWING SUBTOTAL THYROIDECTOMY

To the Editor:—I have a patient who had the thyroid removed in 1937 because of nervousness and insomnia. She is 34 years old and for the past year and a half has been the rounds of doctors, all of whom have tried to assure her that she has no organic heart trouble. Her symptoms, which to her are becoming worse, are palpitation and tachycardia on the least exertion; extreme heart consciousness especially after meals, when she states that her heart *runs away* and she gets nauseated; inability to go to sleep on account of the rapid heart rate and pounding in her chest; constant tightness and dull aching around the area of the cardiac apex, which at times becomes a sharp pain; loss of weight. She has also had two pelvic operations for removal of a cystic ovary. She still has one ovary and there do not appear to be any symptoms of early menopause. Her pulse rate is invariably over 100, and with the least excitement or effort it ranges from 120 to 140 and her blood pressure is as unstable as the pulse rate. She has not had a basal metabolic test for over a year, at which time it was plus 4. Digitalis does not appreciably lower the pulse rate but instead has a tendency to make the patient more apprehensive. Quinidine does have a favorable reaction on the rate and also on the fibrillation. Fluoroscopies have been negative. When the patient is excited there is a perceptible bulge above the thyroid scar to the left, and the neck becomes hyperemic down below the clavicle. Iodides combined with bromides have been tried with some success, but because the iodides caused a skin rash they had to be discontinued. There is no history of rheumatic fever, and as far as I can ascertain with the facilities available here in the country the heart, with the exception of rate and fibrillation, is normal. I have no electrocardiograph available. To my mind this case presents a picture of thyrotoxicosis or a neurocirculatory asthenia. The rest of her physical examination is essentially negative with the exception of prematurely gray hair and myopic astigmatism. What line of treatment would you suggest in this case?

H. L. Shinn, M.D., Hallieford, Va.

ANSWER.—This patient presents an interesting problem. She has either a persistence or recurrence of her thyrotoxicosis or a functional nervous disturbance of some sort with heart damage. The incidence of thyrotoxicosis following a subtotal thyroidectomy for toxic diffuse goiter varies in different clinics from 5 to 15 per cent. Persistence of the disease is much more common than recurrence. In some patients the normal level of basal metabolism is a little below the average, and for them a basal metabolism test within the standard limits may give figures actually a little high. It would be well to determine the basal metabolism level by making several tests on successive days. Iodine or propyl-thiouracil should then be administered to the patient. If she improves a great deal, it may be concluded that her symptoms are the result of thyrotoxicosis. If she does not improve, it may be concluded that they are neurogenic in origin.

DISCOLORATION OF FINGERS AND PORTAL CIRRHOSIS

To the Editor:—A man aged 62 last February had bleeding from esophageal varices. He has been under my treatment for one month. Liver function tests showed considerable impairment of function. The liver was palpable 1 inch (2.5 cm.) under the costal arch. In view of the bleeding and the enlarged liver a diagnosis of cirrhosis was made. The patient was somewhat icteric and had felt ill for a long time. He was put on a diet and a regimen of choline 15 mg. three times a day, vitamin A capsules once a day and liver concentrate twice a week. Under this regimen the patient appears to feel perfectly well and has gained several pounds. One month after he received the choline he noticed a purplish discoloration of tip of his left little finger. On inspection it was found that not only the nail margin but also the tips of all the other fingers of both hands showed the purplish discoloration. There are no symptoms to account for this discoloration. Choline was discontinued one week ago; however, the bluish discoloration has not disappeared. Can you tell me whether choline might produce such an effect? If so, what would be the treatment to produce a constriction of the venules? There is no swelling of the fingers. The Kahn test was negative, the serum bilirubin determination increased considerably.

Eric Lehr, M.D., East St. Louis, Ill.

ANSWER.—It is difficult to give a positive opinion as to the nature and cause of discoloration of this patient's fingers without the privilege of examining him. No primary vascular or cutaneous disease is likely to produce such a clinical picture. If the patient's palms also show a pinkish or violaceous discoloration, it is rather probable that the discoloration of the finger tips is only a part of the palmar erythema, so often associated with portal cirrhosis. The capillary dilatation on which the color changes depend is believed to be related to the failure of the damaged liver to inactivate estrogenic substances, which are normally formed in the body. The urine of such patients may contain increased quantities of free and combined estrogens; in some patients the administration of diethylstilbestrol or similar compounds will cause an increase in the palmar erythema. Incidentally, the discoloration of the palms and finger tips may persist even if there is clinical and laboratory evidence of regression of the primary disease.

It is unlikely that choline has any relationship to the production of the changes described, particularly in view of the small

dose administered in this case. Much larger amounts have been employed for many patients with hepatic disease without the production of anything comparable in the way of discoloration. As long as the fingers are not painful, no treatment would appear to be indicated.

TREATMENT OF VARICOSE ULCER AND HYPERTENSION

To the Editor:—I have a patient aged 63, a man with hypertension of 280 systolic and 130 diastolic. He has severe bilateral varicose veins with an ulcer over the right ankle. The deep veins of the right leg are not patent, and he is not a suitable candidate for ligation of the varicose veins. Wearing an Ace bandage causes discomfort. Is there some method of treatment of the varicose ulcer which can apply pressure without constricting effect? What treatment is recommended for severe hypertension? The heart and lungs and the general condition of the patient are fairly good.

Robert S. Srigley, M.D., Ardmore, Okla.

ANSWER.—The ulcer described must be a postphlebitic ulcer, the result of an old deep venous thrombosis. An additional factor in its persistence is likely to be a diffuse arteriolar sclerosis, which patients at that age and with such a diastolic pressure invariably present. The high pulse pressure is indicative of a rigid, nondistensible aorta unless some other mechanical factor in the aortic valves is present.

Such patients may greatly benefit from glycerin-gelatin casts or elastic adhesive bandages applied over a gauze bandage, never directly on the skin. A few weeks of rest in bed may be necessary to heal the ulcer. The degree of hypertension can be determined by noting the vascular damage in the eyegrounds, in the heart and large vessels, in the kidney and in the peripheral arterial tree. The flexibility of the vascular bed can be determined by the reaction of the blood pressure levels to barbiturates. On the basis of these observations one may decide on surgical, medical or dietary treatment.

From the data submitted it is likely that, outside of much rest, barbiturates and a low sodium diet, no form of therapy is of decided benefit in this particular instance.

MERCURY IN DOMESTIC WATER SUPPLY

To the Editor:—A metal tank is used as a reservoir for a domestic water supply for a household. This tank has been used as a storage tank at a mercury mine for the storage of mercury concentrates. It has been thoroughly cleansed, scrubbed and irrigated. A reputable analytical chemist reports an analysis of water run through it showing mercury present in the concentration of 2 parts in one million. Is this water safe for drinking purposes and ordinary household use?

Frederick F. Ragsdale, M.D., Paso Robles, Calif.

ANSWER.—By computation it appears that the daily intake of mercury for an adult will approximate 1 mg. If true, this falls within the safe limit for mercury intake as devised by the American Standards Association. This standard is specified for inhalation of mercury vapors or dust, this form of exposure being regarded as more significant than the oral intake of the same quantity of mercury. A further safety factor derives from the probability that continued use of this water tank will lead to a day by day decrease in the mercury content of the water. Contrariwise, it is to be recognized that mercury and particularly metallic mercury is treacherous in that variations in temperature or pH may alter the quantity present in the water content of the tank. If this tank is stationed indoors and if it may be presumed to contain hidden pockets of metallic mercury, it should not be allowed to dry out, particularly if surrounding temperatures are relatively high. Metallic mercury readily evaporates. To introduce an additional factor of safety it might be well again to scrub this tank, employing a calcium polysulfide solution (2.5 per cent) or, if this is not available, to scrub with the ordinary lime sulfur mixtures employed in fruit tree sprays. It is the intent of this reply to minimize probability of substantial prospective exposures to mercury provided there are no lurking pockets of mercury as yet undetected.

THE RH FACTOR

To the Editor:—Would you please discuss the following hypothetical case: A primigravida has Rh-negative blood, and her husband has Rh-positive blood. What are the probabilities of having trouble with Rh incompatibility in her first child? In later children? Is cesarean section at 8 months advisable in this or subsequent pregnancies with the hope of discouraging the production of anti-Rh bodies and getting good babies?

Dorr H. Burns, M.D., Chicago.

ANSWER.—Congenital hemolytic disease (fetal erythroblastosis) is extremely rare in the first child except when the mother had a previous transfusion or abortion. Potter (Rh, Year Book Publishers, 1947, p. 120) found the disease only in 3 first-born children in the absence of a known cause for earlier

maternal immunization among 122 Rh-negative mothers who gave birth to infants with hemolytic disease. The incidence was increased from 1 in 42 in second pregnancies to 1 in 12 in fifth pregnancies. Opinions are divided regarding the advisability of cesarean section as a means of protecting the fetus from injury by maternal antibodies. It seems that in most instances damage to the fetus begins early in pregnancy and that the handicap of prematurity is an added burden. It is possible that the recently introduced treatment of the newborn baby by replacement transfusion will improve the outlook for babies delivered by section.

CUTANEOUS TUBERCULOSIS

To the Editor:—I have 2 cases of rosacea-like tuberculid of Lewagowski. Both cases were confirmed by biopsy, and both cases are rather severe. Is there anything new that you can recommend for these unfortunate persons? Is calciferol or streptomycin of any value in these cases?

William L. Dobes, M.D., Atlanta, Ga.

ANSWER:—Streptomycin has been used in the treatment of cutaneous tuberculosis in only a few patients. The results reported by Hinshaw, Pyle and Feldman (*Am. J. Med.* 2:429, 1947), suggest that the improvement that followed has been temporary or questionable. In the treatment of 1 patient with intractable lupus vulgaris the results were said to be excellent. Obviously many patients with cutaneous tuberculosis need to be studied after treatment with streptomycin and followed up to observe the results.

Calciferol has been used with encouraging results. The dosage has varied from 50,000 to 150,000 units a day for a period of several months. The one caution that must be observed in the use of large amounts of calciferol is the toxic manifestations of high dosages of vitamin D₂. They consist of anorexia, nausea, vomiting, a feeling of depression, albuminuria and renal insufficiency. All patients who are treated with high dosage schedules should be followed carefully for signs of intoxication.

MORPHINE AND PAPAVERINE

To the Editor:—What is the safe dosage range and method or technic for administering morphine sulfate and papaverine intravenously?

M.D., New York.

ANSWER:—The intravenous dose of morphine sulfate in shock is from 10 to 15 mg. ($\frac{1}{4}$ to $\frac{1}{2}$ grain), conveniently as the U. S. P. morphine sulfate injection, usually available as 10, 15, 20 and 30 mg. in 1 cc. If it is injected slowly, perhaps in two or three minutes, the toxicity is not materially greater than with hypodermic injection. The 10 mg. dose could be repeated once in an hour if pain is not sufficiently obtunded.

The intravenous dose of papaverine hydrochloride is stated by the U. S. P. XIII as 30 to 100 mg. ($\frac{1}{2}$ to $1\frac{1}{2}$ grains) by mouth or by vein. The intravenous dose against colic is 5 to 30 mg. ($\frac{1}{4}$ to $\frac{1}{2}$ grain). It was also proposed as a test of circulation time, by the deep inspiration which follows when 40 mg. is injected in one second into the cubital vein. The results are not very reliable. Rapid injections are apt to produce nitritoid symptoms, with fall of blood pressure. For therapeutic purposes it is desirable to take one to five minutes for the injection. No serious effects have been reported. It may be injected as the U. S. P. papaverine hydrochloride injection, usually available as 30 mg. in 1 cc.

URINARY TRACT TUBERCULOSIS

To the Editor:—In what per cent of cases of urinary tract tuberculosis are the patients secondarily infected by organisms other than the tubercle bacillus, and about what per cent of patients with genital tuberculosis also have urinary tract tuberculosis?

Perry D. Melvin, M.D., Miami, Fla.

ANSWER:—1. Not much information is available on the incidence of mixed infection. Nesbit, Keitzer and Lynn, in the *Journal of Urology*, September 1945, stated that one third of 260 patients with tuberculosis of the urinary tract were found to have an infection by a secondary organism during a five year observation period.

2. Almost all cases of genital tuberculosis are said to involve also tuberculosis of the urinary tract. The figures vary somewhat, and the mode of development is not agreed on, but certain data are pertinent: The origin of most renal and some genital lesions is hematogenous. In addition, males can and usually do infect the urinary passages from genital foci, and the converse also readily occurs. Tubercle bacilli may almost always be isolated from the urine of males with genital tuberculosis. Females only rarely transmit the infection between the genital and urinary systems, by contiguity. In one series of patients with renal tuberculosis an abnormality of the genitalia was found in 95 per cent.

OCCIPITAL HEADACHE IN A SINGER

To the Editor:—This is a question concerning sudden occipital headache in a singer. He is a tenor, aged 37 and in good health. While singing in a choir and "holding a high note" he felt sudden severe pain in the back of his head; "the walls seemed to come toward him"; he felt weak and had a dull headache afterward. Three days later during similar circumstances he had a like episode. The patient sings with his throat and not his abdomen. Could venous return have been impeded enough to cause a generalized intracranial pressure? Could he have ruptured a small aneurysm? Do such accidents occur often in singers? Is there any prophylaxis? What is the prognosis for further attacks? I should like a list of references for study.

M.D., Pennsylvania.

ANSWER:—The most likely explanation for the syndrome described appears to be a spasm of the muscles of the occipital and posterior cervical area, secondary to prolonged contraction. Similar painful phenomena are not infrequently noted as the result of prolonged contraction of muscles elsewhere in the body. It is possible, but less likely, that a ruptured nucleus pulposus of the upper cervical area may produce this phenomenon. Generalized intracranial pressure would be unlikely to produce sudden, severe pain localized to the occiput. It is doubtful that the singer ruptured a small aneurysm on two occasions without severer complications. Prophylaxis probably depends on more relaxation of the muscles in that area without throwing the head backward to such an extreme degree. As far as is known, there are no specific references on this subject.

HERPES OF THE PENIS

To the Editor:—A man aged 40 has had recurrent herpes on the shaft of the penis for several years. Could you suggest what this might be? What is the best treatment for the condition? What might be done to prevent its recurrence? From the history, I do not believe that this is associated with intercourse or contraceptives.

M.D., New York.

ANSWER:—Herpes preputialis is interpreted as a subthreshold infection with a virus which flares up under certain conditions, e. g. local irritation or lowered resistance of the host. Certain individuals develop herpes after the use of a rubber condom. All types of local irritation should be avoided. There is no known cure for recurrent herpes of the penis.

Occasionally circumcision will clear up herpes of the prepuce.

There have been occasional evidences of success through multiple vaccination of the patient, i. e. vaccination with the smallpox vaccine once a week for four weeks.

CHANCES OF DEVELOPING PARKINSON'S DISEASE

To the Editor:—A patient, a young girl, asked me about her fiancé, who gave a history of encephalitis about one year ago. He was told that he had completely recovered. What are the chances of his developing chronic encephalitis (Parkinson's) and how can it be determined in advance?

M.D., New York.

ANSWER:—The chances of developing late sequelae of encephalitis cannot be stated accurately. Presumably the chances are relatively small if the neurologic signs and symptoms at the time of the acute infection were minimal and if no signs or symptoms remain. Direct evidence of possible future sequelae, such as Parkinson's disease or epilepsy, might be furnished by the electroencephalograph. Abnormalities of rhythm, especially if focal and persistent on repeated examinations, would warn of possible trouble in the future.

BRACHIAL NEURALGIA

To the Editor:—The *Journal*, September 13, page 132, discusses a query regarding pain in the right upper arm. The history of pain in the upper arm following trauma with no relief from ordinary therapy suggests brachial neuralgia or neuritis as stated. Brachial neuralgia is a common cause of painful shoulder, but because this diagnosis is not often made the treatment is generally ineffective. In the case cited the pain in the upper arm is probably a referred pain, so that local therapy could be of no avail.

The treatment should be brachial block with 5 to 10 cc. of a fresh solution of 1 per cent procaine hydrochloride repeated at three, seven and fourteen day intervals, depending on the degree of pain. Six to ten treatments will be required. If results are not obtained from the first few injections, orthopedic consultation or a complete neurologic examination is in order.

In brachial neuralgia the first treatment usually produces gratifying results. The block with its analgesic effect permits the patient to move the arm in a wider range. This gradually breaks up the scar tissue which results from trauma and disuse. The vicious cycle is broken by the block. Diathermy following injection treatment is of benefit, and the patient then carries out the subsequent required manipulation.

F. X. Krynicki, M.D., Detroit.

BCG VACCINATION IN ALL AGE GROUPS

Methods and Results of a Strictly Controlled Study

SOL ROY ROSENTHAL, M.D.
ELEANOR I. LESLIE, M.D.
and
ERHARD LOEWINSOHN, M.D.
Chicago

A radical change in our thinking in regard to BCG vaccination has been initiated by the United States Public Health Service under the guidance of Dr. Herman E. Hilleboe, one time Assistant Surgeon General, with the approval of Surgeon General Thomas Parran. Under the auspices of the United States Public Health Service, a conference on BCG was held in Washington on Sept. 7, 1946.¹ This representative body, composed of proponents and opponents of BCG vaccination, concluded and recommended essentially as follows:

"A. Medical literature fails to reveal any proven cases of progressive disease as a result of BCG vaccination.

B. From studies presented at the conference, it appears that BCG vaccination confers increased resistance to tuberculosis for the limited period of time covered in these studies.

C. Extensive investigations should be carried on cooperatively with recognized research groups throughout the country during the coming years, especially in population groups highly exposed to tuberculous infection.

D. It was recommended that a single laboratory be established by the Tuberculosis Control Division to produce BCG vaccine for the whole country for use in research programs proposed at this conference.

BCG (*Bacillus* of Calmette and Guérin) is a non-virulent bovine tubercle bacillus originally isolated from the milk of a tuberculous cow in 1906. The virulence of this organism was then reduced by the regular transfers on a bile potato medium over a period of thirteen years. The avirulent organism was able to produce local nodular lesions in animals, but there was no evidence of progression or generalization of the process. It was then discovered that these animals when infected with virulent tubercle bacilli resisted a progressive infection to a great extent. With the assurance that the organism was harmless and that it afforded a certain degree of protection against virulent tubercle bacilli,² human application was instigated in 1921 by Weill-Hallé in

Paris.³ Since that time it is estimated that some ten million vaccinations have been performed throughout the world.

The reluctance to accept BCG in the United States stems largely from the laboratory studies of Petroff and the tragedy in Lübeck, Germany. Petroff and his co-workers⁴ dissociated BCG into rough "R" and smooth "S" forms. The latter, it was claimed, had the ability at times to produce progressive disease in animals.⁵ One of us (S. R. R.), working in an isolated laboratory where only BCG was cultured, using many thousands of cultures and animals over a period of thirteen years, has been able to dissociate BCG but has never seen progressive disease following BCG inoculation in any phase.⁶ As much as three hundred thousand times the human dose, calculated by weight, has been injected into animals without deleterious effect.⁷ Petroff, in a personal communication in 1934, conceded at that time that BCG was probably a pure "R" form and as such incapable of producing progressive tuberculosis.

The disaster that occurred in Lübeck, Germany, was one in which 271 infants received what was supposed to have been BCG vaccine by mouth. Seventy-seven died of progressive disease following ingestion of this mixture. It was later proved by the Robert Koch Institute of Berlin for the German government that the vaccine used was a mixture of BCG and a virulent strain of tubercle bacilli which was kept in the same incubator as BCG. The virulent strain in question was received from the nearby town of Kiel, and was readily identified by its peculiar characteristic of producing a phosphorescent green color in Sauton medium. For this act of malpractice, those responsible were imprisoned.⁸

The following study has been in continuous operation for thirteen years and constitutes the longest continu-

ous experiment in the United States. The first three years were spent entirely on research in animals, and during the last ten years human beings of every age group have been vaccinated. This study is unique in that: (1) the controls represent a population similar to the vaccinated, and (2) the principle of isolating the vaccinated person until the tuberculin test became positive in result was practiced when tuberculosis was present in the household. In the latter group, controls were isolated for similar periods of time. The major premise of this study was that BCG should supplement present methods of early diagnosis and segregation.

GROUPS STUDIED

1. *Newborn Infants Delivered at the Cook County Hospital of Chicago.*—Arrangements were made with the mothers in the prenatal clinic so that enough time was available to examine roentgenologically each member of the household. The children in this group came from households in which there was no known tuberculosis as demonstrated by roentgen examination of each member. The infants were vaccinated or accepted as controls before they left the hospital, and no isolation was practiced. This study has been in progress for ten years.

2. *Infants Born of Tuberculous Parents Anywhere in Chicago.*—Isolation of the infants was practiced for the controls and vaccinated alike, usually from six to twelve weeks, depending on the severity of the disease. Children were returned to their families only if examinations of concentrated sputum of the tuberculous member, within six months, were negative in result. This group has been followed for seven years.

3. *Student Nurses at the Cook County Hospital (With Drs. Rhodes and Afremow).*—Students were tuberculin tested and vaccinated during their first week in training. They were not allowed to go onto ward for at least one month after vaccination. This study has been in progress for seven years.

4. *Medical Students at the University of Illinois.*—These students were examined roentgenologically and tuberculin tested at the end of their first year or the beginning of their second year. The negative reactors who desired vaccination were vaccinated. Those who refused vaccination were used for the control group. This group was begun seven years ago.

5. *Children in a Federal Housing Project.*—The entire community was first examined roentgenologically and those with active pulmonary disease were isolated. Alternate children up to 10 years of age who did not react to tuberculin were vaccinated. This study is now in its sixth year.

6. *Inmates of a Mental Institution.*—After a roentgen survey and tuberculin testing, the persons with active disease were isolated. Seven months later the negative reactors were again tested. Alternate negative reactors were vaccinated. All age groups were included. This study was initiated four years ago.

The ensuing report embraces for the main part groups 1 and 2. Groups 3 to 6 are only mentioned, as some of the final results are not available, and they will be published in detail elsewhere.

THE VACCINE

The cultures used for the vaccine are transfers from the original culture at the Pasteur Institute in Paris. These were brought over by one of us (S. R. R.) in

March of 1934 and have been transferred continuously every two weeks since that time. For each batch of vaccine, virulence studies are made in animals. The reactions in animals and the growth characteristics of this organism have not appreciably altered during this thirteen year period. The type of lesion produced in animals and the rapidity of development of a tuberculin action in animal and man remain the same. The vaccine is gathered from the growth on synthetic mediums (Sauton) and is a suspension of bacilli in a buffered salt solution. The vaccine is put up in capillary tubes in much the same way as is done for vaccinia.

METHOD OF APPLICATION

The oral method of administration originally advocated by Calmette and used by Weill-Hallé⁹ was largely replaced by the intracutaneous route suggested by Wallgren.⁹ The former method yielded a small percentage of reactors to tuberculin, while the latter yielded a high percentage. However, the local sequelae following the intracutaneous method were: ulcerations which may persist for months, focal abscesses and suppuration of lymph nodes. In a recent report from Denmark by Holm¹⁰ universal ulceration was reported following intracutaneous vaccination. In 26 of 3,369 vaccinations, local abscesses or suppurated lymph nodes developed. Residual scars were the rule. A similar experience was reported in the study with Indians in this country by Aronson.¹¹ It is obvious that it would facilitate the generalized use of a vaccination if complications could be eliminated. To this end one of us (S. R. R.) described the scarification method of multiple punctures.¹² In thousands of vaccinations by this method complications have been practically nil. The actual technic is as follows:

A drop of vaccine is placed on the outer aspect of the alcohol-cleansed arm. A sewing type needle, similar to the one used for vaccinia, is held between the thumb and the index finger about 1.5 cm. from the point. The thumb and needle should form a continuous line. With the shaft of the needle held tangentially to the skin, the vaccine is spread in linear fashion for a distance of 2.5 cm. By a downward pressure, exerted to a large extent by the thumb, the skin is pierced with the needle point through the vaccine. Following this downstroke, which engages the point of the needle into the skin, an upward movement is exercised without disengaging the needle. The point of the needle remains buried in the skin on the upstroke. This precaution makes the method foolproof. The punctures are placed about 2 to 4 mm. apart, and ten punctures are made in a line. The vaccine is spread to the second line parallel to the first and 4 to 6 mm. away. Thus three lines of ten punctures each are made in an area of approximately 2.5 by 1.5 cm. The vaccine is allowed to dry on the arm; no blotting or covering with dressings is practiced. Wetting of the arm should be avoided for twenty-four hours.

The lesions following the multiple puncture method in newborn infants resembles goose flesh after two to six weeks following vaccination. The mother rarely knows which arm was inoculated. In children and adults each puncture progresses to form pink papules from a pinhead to 3 mm. in size. These papules after four to eight weeks regress rapidly. The recipient is

usually unaware of which arm was scarified. The draining lymph nodes may be palpable two weeks after vaccination, but never enlarge to the extent that the recipient is aware of it. Ulceration and breaking down of lymph nodes have never been seen.

In a special study made to determine how soon the tuberculin reaction becomes positive after vaccination at birth, it was found that none reacted before ten days (37 cases). Out of 57 tested at eleven to thirteen days, 8, or 14 per cent, reacted; of 30 tested at twenty-three to thirty-one days, 29, or 96.6 per cent, had positive reactions and of 53 tested at thirty-two to fifty-four days, 51, or 98.1 per cent, reacted positively. In young adults 50 per cent react to 1 mg. of old tuberculin in one week and 90 per cent in two weeks. Table 1 gives the results of tuberculin reaction in children, all vaccinated on the third to seventh day of life. The Vollmer patch test was done in these cases and, if negative in result, was followed by the Mantoux test, 1 mg. of old tuberculin being used. As the table shows, the tuberculin reactions continue to be positive in over 90 per cent of the cases up to four years and in about 80

high incidence of casual infection and the degree of exposure for the vaccinated and the control groups.

In older children and adults the duration of tuberculin reactions following a single vaccination was similar as far as they were tested (88.6 per cent of the 35 nurses tested reacted after three years).

EFFICACY OF THE VACCINATION; GROUP I

There was but 1 person who was hospitalized for tuberculosis in the vaccinated group compared with 15 for the controls. Considering roentgen evidence of disease such as parenchymal infiltration, hilar infiltration and calcification, there were 11 cases in the vaccinated and 39 in the control group. There was 1 death in the vaccinated as compared with 7 in the control group (table 3).

The clinical course and the postmortem findings of the vaccinated child that died revealed progressive

per cent after six to six and a half years following a single vaccination. These results are equal or superior to those obtained when other methods of introducing the vaccine are used. This has been verified by Nègre and Bretey¹³ and Weill-Hallé¹⁴ of France, Birkhaug of Norway,¹⁵ Wallgren of Sweden,¹⁶ and Etcheverry,¹⁷ Gines and Rebull Richieri of Uruguay.¹⁸

For comparison, table 2 lists the controls for this group. It will be noted that there is a high rate of tuberculin reaction conversion. This is not surprising in that children included in this part of the study come from the poorest districts of Chicago, where the tuberculosis death rate is high. The high tuberculin reaction conversion of the controls is of special interest in that members of the household of these children had normal roentgenograms of the chest. This indicates the

primary tuberculosis in the lung and tuberculous meningitis. There were no lesions at the site of BCG inoculation or in the draining lymph nodes. It is noteworthy that six months after vaccination this child failed to react to the first Vollmer patch test and had only a weakly positive reaction on retesting. At fifteen months the patch test again elicited a negative reaction and at eighteen months a weakly positive reaction. In a reconstruction of this case, it can be considered as one which

was at best a "poor take," and more likely "no take." Unfortunately, the mother was not entirely cooperative, so that a Mantoux test could not be performed. The child was eventually taken south, where intractable diarrhea developed. Death occurred soon after his return, at 22 months of age.

A comparison of the incidence of tuberculosis in siblings is given in table 4. Approximately 41 per cent of our entire series in group I were siblings. This constitutes a more exact population for comparison. There were 4 cases of tuberculosis in the vaccinated and no deaths, against 22 cases in the controls with 3 deaths. The morbidity rate per thousand person-years was 5.29 times higher in the nonvaccinated group.

In comparing the time of occurrence of tuberculosis and the type and course of the disease in the vaccinated and in the controls, a distinct contrast is noted (chart 1). There were no cases of tuberculosis in the vaccinated infants 1½ years of age and under, as compared to 9 cases in the controls, 3 of whom died. There were 20 cases of tuberculosis and 6 deaths up to 3 years of age and under in the control group and but 4 cases in the vaccinated. The 1 death has already been discussed.

* Rate per thousand person-years observed.

The duration of the process in the vaccinated group was under one year for all cases, whereas for the controls there were 11 cases out of 25 that presented lesions for longer than twelve months, some lasting over two years (chart 2). Calcification occurred in about 50 per cent of the active lesions of both groups. Six of the 10 controls presented evidence of calcification within two to three years, and 4 not until three to five years. On the contrary, in all 4 cases of the vaccinated group, calcification was noted within two to three years. In addition 3 of the 11 cases in the vaccinated group presented calcification as the first and only roentgen finding as compared to 3 of 39 cases in the controls.

Considering the 7 persons in the control series that died of extensive disease, there were an additional 2 patients in whom the lesions in the lung involved the entire lobe. There were no such cases in the vaccinated group (except the 1 death already described).

From these observations it may be deduced that in the vaccinated group not only is there a suppression of virulent infection, but when infection with virulent organisms does occur, the lesions are less extensive, of shorter duration and calcify earlier than the lesions in the nonvaccinated group.

EFFICACY OF THE VACCINATION, GROUP II

All the children in group II were isolated in foster homes for varying periods of time, depending on the source and the degree of tuberculosis. The control and vaccinated subjects were chosen from a master chart by a person who had only paper knowledge of the cases

of infection. In this way no selection between control and vaccinated could be practiced. The discrepancy in the number of cases in the vaccinated and the control group was due to the fact that during the early trial period varying lengths of time of isolation were experimented with and controls were not included. Subsequent to the establishing of a definite schedule, the cases were alternated. To attest that this is an unbiased

Chart 1.—Incidence of tuberculosis by age groups.

method, a previous study showed that the mother was a source in 58.6 per cent of the vaccinated and 60.3 per cent of the controls; the father in 23.3 per cent and 34.9 per cent respectively. Of the contacts 43.1 per cent had positive sputum in the vaccinated against 39.7 per cent in the controls.

There were 2 cases of tuberculosis in the vaccinated group, in which only 1 patient needed hospitalization, as compared with 5 cases in the control group, in which all patients were hospitalized and 4 died of tuberculosis (table 3). Again recovery in the vaccinated group was within six to twelve months, whereas in the control group the 1 patient that lived had a stormy course for two to three years.

Considering the contact and noncontact group as a whole, there were 13 cases of tuberculosis and 1 death in the vaccinated group as compared with 44 cases of tuberculosis in the controls with 11 deaths.

GROUP III

The student nurses who were vaccinated were allowed to work in the Tuberculosis Hospital, whereas the control negative reactors were not. Notwithstanding the

Chart 2.—Duration of active lesions exclusive of deaths and calcification only. Each circle represents a case. (Insufficient roentgenograms were done in 4 cases; lesions were still present in 3 controls.)

discrepancy in the degree of exposure, in none of the 142 vaccinated nurses, over a period of seven years, did pulmonary tuberculosis develop. In contrast there were 3 cases of pulmonary tuberculosis in the 199 controls. All required bed rest and 2 required sanatorium care. There were 3 additional cases of pulmonary tuberculosis among the tuberculin-positive reactors. Tubercle bacilli were said to have been recovered from a cervical

lymph node of 1 of the vaccinated nurses. She gave a history of drinking raw milk. The lesion did not necessitate hospitalization.

GROUP IV

Medical students at the University of Illinois were first vaccinated in 1939. In the 109 students vaccinated over a four year period, there were no cases of pulmonary tuberculosis. Four cases were reported in the nonvaccinated groups. The complete data are not yet available because of the interruption of the war. Questionnaires are being sent out to obtain more recent information.

GROUP V

In the federal housing project there were 699 children vaccinated and 625 controls who did not react to tuberculin. There were 275 children who reacted to tuberculin at the onset who were not vaccinated. Tuberculin testing and roentgenograms of the chest were done every year. There were no cases of pulmonary tuberculosis in the vaccinated group, whereas among the control negative reactors there were 4 cases of roentgen evidence of the disease, which was considered active in 3. In the tuberculin-positive group there were 2 persons with active tuberculosis of whom 1 died of the disease. Another death from tuberculosis occurred in a child whose tuberculin reaction was not recorded but whose original roentgenogram of the chest was negative. Considering the negative and positive reactors not vaccinated, there were 7 cases of tuberculosis of which 2 were fatal, against no cases of tuberculosis in the vaccinated group.

GROUP VI

Some 4,500 patients at a mental institution were examined roentgenologically and tuberculin tested. Of these 251 did not react to 1 mg. of old tuberculin. The persons with active disease were segregated and the negative reactors were retested seven months later; 84.4 per cent of the 251 had converted. Of the remaining negative reactors, 20 were vaccinated and 15 were kept as controls. In order to identify the vaccinated and the control subjects, they were tattooed with india ink, sterile ink being used and the same type of needle as was used for vaccination. The local reactions to the vaccination did not differ from those described for young adults, although some patients were up to 66 years of age and their habits were unclean. No dressings were used after vaccination. The present status of these patients was submitted by Dr. E. Teller, who was originally associated with this work. There was no pulmonary tuberculosis in the 20 patients vaccinated and 1 case of bilateral minimal arrested pulmonary tuberculosis in 15 controls. The status of the patients was obtained approximately four years following vaccination.

COMMENT

This study represents the longest continuous experiment on BCG vaccination in the United States. From experiences over a period of thirteen years, it can be stated unconditionally that BCG is safe, a fact that has ample verification the world over.¹⁹

The efficacy of the vaccine has been well documented in this study. In newborn infants of the noncontact group, the tuberculosis rate per thousand person-years was 6.46 for the controls as compared with 1.95 for the vaccinated, or 3.31 times greater for the controls. Considering the 1,159 siblings followed for about 2,800 person-years in the vaccinated and control groups, the rate was 5.29 times greater in the nonvaccinated (table 4). The death rate for the noncontact group was 0.17 for the vaccinated and 1.16 for the controls, or 6.8 times greater in the nonvaccinated. In the contact group the proportions were even more in favor of the vaccinated; the tuberculosis rate was 4.56 times higher in the controls and the death rate was 17.60 for the controls against zero in the vaccinated. Because the populations in the groups being compared are similar, this being especially true for the sibling group, the differences in the groups are highly significant from a statistical standpoint.

In an extensive study in Indians, ages of subjects being 1 to 20 years, over a six year period in which no isolation was effected before or after vaccination, the rate per thousand person-years was 4.7 as compared to 24.3 for the controls (Aronson and Palmer^{19a}). Ferguson^{19b} of Canada found that in nurses the ratio of vaccinated negative reactors as compared with nonvaccinated negative reactors was 1 to 4.27. His "controls," however, were from a five year period immediately preceding the initiation of vaccination. No isolation was practiced after vaccination. These studies are cited to demonstrate the results obtained in this country following parenteral administration of the vaccine. They cannot be compared with the work being reported in that the age groups and races are different.

Not only were the morbidity and mortality from tuberculosis appreciably reduced after vaccination, but the extent, severity, duration and sequelae of the pulmonary lesions when they did occur in the vaccinated differed from those of the nonvaccinated. In the former, such lesions were less extensive, of shorter duration and calcified earlier.

The vaccination strives to initiate and maintain a positive tuberculin reaction in the recipient. The question of whether this is desirable has been discussed. The protective action of a naturally produced primary complex that is well healed was well brought out by a survey made by one of us^{19c} and more recently by Marc Daniels for the Prophit Tuberculosis Survey of Great Britain.^{19d} In some twenty reports the world over, the incidence of tuberculosis developing in student nurses (one report included other students) was found by him to be 2.1 per cent (173 cases of 8,202) in those initially positive in reaction to tuberculin as compared to 5.8 per cent (278 out of 4,832) in those originally negative in reaction to tuberculin. In his own study of Great Britain there were 2,120 nursing students originally positive in reaction to tuberculin in 43 of whom, or 2 per cent, tuberculosis developed, against 27 out of 452 negative reactors, or 6 per cent, in whom the disease developed. In children a positive tuberculin reaction following infection with virulent tubercle bacilli may signify a progressive incipient lesion not indicated early by roentgenograms, as well as a current tuberculous environment with opportunities for repeated exposure. In young adults a positive reaction is more likely to indicate a healed primary lesion. It can readily be understood why a positive tuberculin reaction in all children, if caused by natural infection, offers a

prognosis. It would thus seem logical to substitute BCG, which is avirulent and in which the dose can be controlled, for virulent uncontrollable natural infection.

Another timely question is: What portion of our population should receive BCG vaccination? This and other studies indicate that for the time being, at any rate, those who benefit most by the vaccination are susceptible races (such as Negro and Indian) and those unduly exposed to tuberculosis of all races, in all age groups. It is again stressed that those who are vaccinated should have a period of at least one month before and after vaccination when there is no direct contact with virulent tubercle bacilli.

It has been stated that the decline in the death rate from tuberculosis in the United States has been so precipitous (from 194.4 to 40.1 per hundred thousand in 1900 and 1945 respectively)²⁰ that no further measures are needed to reduce the incidence of the disease other than those that are already in practice. In 1926 the rate for 1940 was predicted to be 20 per hundred thousand²¹; in 1941 it was predicted that substantial elimination of the disease was in sight by 1960.²² These predictions have fallen pitifully short of their goal. Granted that the death rate from tuberculosis for all ages is seventh on the list of deaths from all causes, between the highly productive ages of 18 to 40 years it ranks first. Some supplement, therefore, is definitely needed to augment our present methods of tuberculosis control.

The need for BCG vaccination will probably become more and more important as the incidence of tuberculosis drops, for we may again approach a relatively virgin soil in human beings for the tubercle bacillus. What may happen in a susceptible people is illustrated in a small tuberculosis epidemic that occurred in a secondary girls' school in Denmark in pupils aged 12 to 19 years.¹⁰ In January and February of 1943 an influenza-like epidemic broke out, and because there was associated erythema nodosa, tuberculosis was suspected. Fortunately, a tuberculosis control program had been in effect for some years, and the status of each pupil was known as regards the tuberculin reaction and roentgenogram of the chest. Before the outbreak it was known that of the 368 students, 130 were tuberculin positive in reaction, and 105 tuberculin negative, and 133 had been vaccinated with BCG. Of the 105 tuberculin-negative reactors, 70 converted during a period of a few months; of the 70, 41 showed roentgen changes, and of the latter tubercle bacilli were demonstrated in 37. There were 7 cases of definite pulmonary disease, or 6.7 per cent. Of the 133 vaccinated with BCG, there was pulmonary disease in only 2, or 1.5 per cent, whereas in the naturally positive reactors there were 4 cases, or 3.5 per cent. The source case was found to be a female teacher in whom minimal processes were demonstrated in one apex together with a positive gastric lavage. She taught class in a badly ventilated basement room. It is of interest that the rate of conversion was high not only in those pupils whom this teacher taught, but also in those pupils who occupied the same room but were not in contact with the teacher in question. The cases

of genuine pulmonary tuberculosis, of which there were 13, practically all occurred in the teacher's own class (12 out of 13). Better than 50 per cent of all the pupils in the initially tuberculin-negative, BCG-vaccinated and initially tuberculin-positive groups were exposed to the infected teacher. The percentage of conversion in the originally tuberculin-negative reactors was 86.8 per cent for those in contact with the teacher and 58.5 per cent for those in her classroom only.

In vaccinated adults and children in the Tice Laboratory study, no pulmonary tuberculosis occurred after three to seven years, whereas the expected morbidity rate was noted in the controls. This is a preliminary report for these groups.

The persistence of the tuberculin reactivity following a single vaccination in newborn infants was almost universal up to three and one-half and four years and practically 80 per cent after six and one-half years. In young adults it was 88.6 per cent after three years. It cannot be definitely stated that the results obtained in this study as far as the reaction to tuberculin was concerned were due entirely to the vaccination, as a high degree of conversion occurred in the controls soon after they entered this study.

The application of the vaccine by the multiple puncture scarification method has minimized the complications to a negligible level. This, plus the fact that the vaccine and the scarifying needle are put up in capillary tubes much the same as for vaccinia, makes this form of vaccination admirably suited for general use.

The United States Public Health Service has selected the Tice Laboratory as the central one for the production of BCG for its use. In this capacity the Tice Laboratory has supplied vaccine for the government BCG vaccination programs in Georgia and in Michigan.

SUMMARY

The application of BCG vaccination to all age groups is a safe and effective procedure.

In 2,831 newborn infants living in the poorest districts of Chicago but not in household contact with tuberculosis, there were 11 cases of tuberculosis in the vaccinated against 39 in the controls. The rate per thousand person-years was 3.31 times as great in the controls as in the vaccinated. There was 1 death from tuberculosis in the vaccinated against 7 in the controls, or a difference in the rates of 6.8 times.

In 1,159 siblings the tuberculosis rate per thousand person-years was 5.29 times as great in the controls as in the vaccinated.

Among 256 newborn infants, when tuberculosis was present in the household and when isolation in foster homes was practiced in the controls and vaccinated alike, there were 2 cases of tuberculosis in the vaccinated as compared to 5 in the controls. The rate was 4.56 times as great in the controls. There were 4 deaths in the controls and none in the vaccinated.

Considering the noncontact and contact groups as a whole, there were 13 cases of tuberculosis with 1 death in the vaccinated group as compared to 44 cases of tuberculosis with 11 deaths in the controls.

In a preliminary report on children in a federal housing project, in nursing and medical students and in patients of all ages in a mental institution, there were no cases of pulmonary tuberculosis in the vaccinated group followed for three to seven years. The expected tuberculosis rate was present in the control groups.

22. Dublin, L. I.: 1941 Closes with Distinctly Good Health Record, a per-
nate 14: 35-37, 1942.

By the use of the multiple puncture method, practically all complications were avoided; tuberculin reaction conversion was rapid (within one month) and universal.

A positive tuberculin reaction following a single vaccination was present in 92.6 per cent after three and one-half to four years and 79.85 per cent after six to six and one-half years in children vaccinated at birth and 88.6 per cent in student nurses at the end of their training, three years after vaccination.

ROLE OF TRANSFUSION IN THE ETIOLOGY OF ERYTHROBLASTOSIS

A Warning to Physicians

L. M. HELLMAN, M.D.

and

G. R. VOSBURGH, M.D.
Baltimore

Since the role of the Rh factor and isoimmunization in the production of erythroblastosis was first pointed out by Levine¹ and Wiener² more than seven years ago, this phenomenon has been of great concern to the physician and layman alike. It is amazing that such widespread interest should be centered on a disease which is extremely rare, since clinically recognizable erythroblastosis fetalis probably does not occur in the usual obstetric clinic in more than 1 in 300 deliveries; and, inasmuch as the infant mortality from this disease is in the neighborhood of 50 per cent, it can be estimated that the chances of an infant dying from this condition are less than 1 in 600 deliveries. The theory enunciated by Levine is simple and straightforward. If an Rh-positive man is married to an Rh-negative woman, which combination makes up about 12 per cent of the marriages, the infant will in the majority of instances be Rh-positive. The woman, being Rh-negative, is capable of being sensitized or producing antibodies to the Rh-positive cells of her unborn child and, thus, when these antibodies cross the placenta they hemolyze the blood of the infant, producing the varied manifestations of erythroblastosis. The immunology of isoimmunization and the genetics of the Rh factor have provided a fertile field for many investigators whose names are well known. A point which has been mentioned only casually by Levine³ and Diamond,⁴ but has not received the emphasis it deserves, is the role of transfusion in the production of this syndrome. This is all the more pertinent because of the recent development of blood banks and the more and more frequent use of transfusions. The great increase in the number of transfusions given at the Johns Hopkins Hospital is illustrated by the fact that 1,100 transfusions were given in 1939 as compared with 5,585 in 1946, a fivefold increase.

There are but two ways by which an Rh-negative woman can be sensitized to Rh-positive cells and thus give birth to an erythroblastotic child. The first of these is by repeated bearing of Rh-positive children.

This process gives her a gradually ascending titer of Rh antibodies, producing after several pregnancies mild and then more and more severe erythroblastosis. In such an event her first and often her second child are spared. The second means by which such a woman may become sensitized is by the administration of an Rh-positive transfusion. This will produce no outward reaction if she has not been previously immunized but serves as a much more powerful immunizing agent than the repeated bearing of Rh-positive children. Even a small transfusion will give a high and persistent antibody titer. Women so sensitized produce Rh-positive children with the severest form of erythroblastosis who usually do not survive. If they are in the 38 per cent who have homozygous Rh-positive husbands, they will be fortunate indeed to have 1 living child. Since 1937 there have been 27 cases of erythroblastosis in the Department of Obstetrics of the Johns Hopkins Hospital. These are shown graphically in table 1. The incidence in that year was 1 in 1,732 deliveries, while in 1946 the incidence was 1 in 348 deliveries. It is doubtful that the diagnosis was missed during that period, and while the apparent increase in incidence

TABLE 1.—Incidence of Erythroblastosis, Johns Hopkins Hospital, 1937-1946

Total	19,160	27	710

may be due somewhat to selection of cases for admission, it must also be admitted that there may be a real increment in the incidence of the disease. Since the percentage of Rh negativeness in the population is fixed, such an increment must be due to an increase in the incidence of sensitization of the mothers, and such a phenomenon may well be related to the increased incidence of transfusion known to have taken place. Of the 27 cases of erythroblastosis, the 7 following gave a history of transfusion:

HISTORIES OF CASES

CASE 1.—The patient was a 40 year old para 3-3-0-0-1.⁵ Her first child was delivered in 1927 by cesarean section because of premature separation of the placenta. The child was never in good condition and died at 18 months of life. After the operation the patient received one transfusion. Her second child was delivered in 1937 by low forceps. It weighed 2,370 Gm. and was jaundiced and anemic at birth. It received a few transfusions while in the hospital and was discharged weighing over 3,000 Gm. Soon after going home it was found dead in its crib; it presumably died of some cerebral damage due to erythroblastosis. Her last child was delivered in 1939 by low forceps and weighed 2,890 Gm. At birth it had 1,890,000 red cells per cubic millimeter and was jaundiced. It received multiple transfusions and survived and is living and well today.

CASE 2.—The patient was a 34 year old para 2-2-0-0-1 whose first pregnancy in 1942 terminated in a stillborn infant, the

5. The numbers following para indicate in order total pregnancies, full term infants, premature infants, abortions and living children.

fetus having died in utero on the day before the onset of labor. She had a postpartum hemorrhage because of an adherent placenta and was given one blood transfusion. She was Rh-negative and her husband homozygous Rh-positive. Her second pregnancy in 1944 terminated in a living infant which had pronounced erythroblastosis with anemia and jaundice. This infant was successfully treated by repeated transfusions and is now living but is spastic. She was seen for this pregnancy at about the tenth week, at which time she showed blocking antibodies (4 plus) with glutinins of 96 units in plasma. Because of the uncertainty of another erythroblastic child the pregnancy was interrupted.

CASE 3.—The patient was a white primigravida aged 20 whose delivery was due by dates in December 1945. She was Rh-negative and her husband was homozygous Rh-positive. She received two transfusions for severe epistaxis in 1943. She was delivered by low forceps on November 10 of an edematous and jaundiced infant. The child did not survive more than two hours in spite of multiple transfusions.

CASE 4.—The patient was a 32 year old para 2-2-0-0-1. She was Rh-negative and her husband was homozygous Rh-positive.

CASE 6.—The patient was a 30 year old para 2-2-0-0-1 who was delivered in 1934 of a normal Rh-positive infant. She was Rh-negative and her husband homozygous Rh-positive. In 1941, after a pelvic operation, she was given one transfusion. During her present prenatal period blocking antibodies (3 plus) and a glutinin titer of 512 units in plasma developed. She was delivered at term in September 1945 of a living 3,230 Gm. infant which had congenital hydrops, jaundice and anemia. There were gross placental changes. The child did not survive more than two hours and the diagnosis of erythroblastosis was confirmed at autopsy.

CASE 7.—The patient was a 22 year old primigravida who at the age of 2 months received one transfusion of 170 cc. of blood for dysentery. She was Rh-negative and her husband was heterozygous Rh-positive. Her due date in the present pregnancy is March 1946. On February 22 she showed a glutinin titer of 24 units in plasma. She also had blocking antibodies (4 plus). She was delivered on February 28 of a 3,120 Gm. male infant in good condition. The baby became jaundiced at 5 hours and showed both agglutinins and glutinins in its plasma.

* Cells suspended in plasma.

† Prognosis for future normal children as determined by genotype of husband (homozygous 0 per cent; heterozygous 50 per cent).

‡ Premature separation of placenta.

§ Postpartum hemorrhage.

¶ Suspension of uterus.

Eight years prior to the present pregnancy she was delivered of a normal Rh-positive child. One year later she had a partial gastrectomy for a duodenal ulcer and at that time she had three transfusions. To each of these she had a severe reaction. Near term in the present pregnancy she had glutinin titer of 64 units and blocking antibodies (4 plus). She was delivered by low forceps of a 3,200 Gm. child in poor condition. The child had severe jaundice and low hemoglobin level and in spite of repeated transfusions did not survive. The diagnosis of erythroblastosis was confirmed at autopsy.

CASE 5.—The patient was a 38 year old para 3-3-0-0-3 who through a laboratory error was thought to be Rh-positive. Her first child, born in 1939, and a second, born in 1942, were both Rh-positive and were living and well. Following her second delivery she had a postpartum hemorrhage for which she received one transfusion. She was delivered at term by low forceps of a 3,120 Gm. child in November 1946. The child was in poor condition and showed decided pallor and some jaundice at birth. The diagnosis of erythroblastosis was made and confirmed by examination of the infant's blood. On reexamination of the patient she was found to be Rh-negative and her husband was homozygous Rh-positive. She had a glutinin titer of 64 units. The child was severely ill and after receiving multiple transfusions and a long hospital stay left the hospital in good condition.

The jaundice was never severe and serious anemia never developed. It was discharged from the hospital without requiring any transfusion.

The summary of these cases can be seen in table 2. The following 2 cases represent Rh-negative women with heterozygous Rh-positive husbands and a carry-over of agglutinins from the transfusion. They are added to table 2 although they gave birth to normal Rh-negative infants.

CASE 8.—The patient was a 27 year old primigravida who was given two blood transfusions for anemia and arthritis in 1942. She was Rh-negative and her husband was heterozygous Rh-positive. In addition to the transfusions in 1942 she was given another transfusion in 1945, at which time she had a severe reaction with hematuria. During this pregnancy a glutinin titer of 192 units developed, and she had blocking antibodies (4 plus). She was delivered at term in November 1946 of a 3,480 Gm. infant which was Rh-negative and which showed no erythroblastosis.

CASE 9.—The patient was a 26 year old para 2-2-0-0-2 who was Rh-negative and whose husband was heterozygous Rh-positive. She was delivered in 1944 of a normal infant which is living and well. The delivery was followed by a postpartum

hemorrhage for which she received one transfusion. During this pregnancy she showed blocking antibodies (4 plus), but more than 12 units of glutinin never developed. She was delivered at term in January 1947 of a 3,090 Gm. Rh-negative infant in good condition.

Nine Rh-negative women are presented who had received previous blood transfusions and who subsequently delivered children with erythroblastosis or in whom antibodies developed which endangered their future childbearing careers. These 9 women had had 5 normal children prior to their transfusions but had only 2 normal infants thereafter. Both the normal children born after transfusion were Rh-negative, these women having heterozygous husbands. The patients with homozygous mates had no normal children after transfusion, and of the 8 erythroblastotic infants born to them the expected survival of 50 per cent occurred. Hence the subsequent childbearing of all these patients had been seriously jeopardized, especially those with homozygous husbands. At least 1 of these latter has requested and received sterilization for this reason.

It might well be argued that all but 3 of these patients had one or more pregnancies prior to the transfusion

TABLE 3.—Interval Between Transfusions and Birth of Erythroblastotic Child in Seven Patients

Patient	Age at Transfusion	Year of Transfusion	Number of Transfusions	Interval to Birth of Erythroblastotic Infants, Years
3.....	17	1943	2	2
2.....	30	1942	1	2
5.....	34	1942	1	4
6.....	25	1941	1	5

1.....	21	1927	1	10
7.....	2 months	1925	1	21

and that the pregnancy alone might well be sufficient to immunize them. Certainly this fact cannot be denied, but it is interesting to note that a history of previous transfusion occurs in but 2 per cent of our patients, while in the 27 instances of erythroblastosis a history of transfusion was present in 7 women or 26 per cent; and all in all the evidence is strong that transfusion does play an important role in the production of erythroblastosis. With the increased use of transfusion the chance of unwittingly administering Rh-positive blood to Rh-negative women is definitely increased. Since such transfusions may be disastrous to future childbearing, even though many years may intervene, they can only be regarded as reprehensible; and in our opinion a high degree of negligence may be charged if transfusion is ever given to a female child, or woman in the childbearing age, without first determining the Rh compatibility. In cases of dire emergency when time does not permit Rh determinations, only Rh-negative blood should be given.

CONCLUSION

The obstetric experiences of 9 Rh-negative women are reviewed who gave histories of previous blood transfusions. As the result of these transfusions the subsequent childbearing careers of these patients were gravely jeopardized. There is need to reemphasize the fact that Rh compatibility should be determined for all females prior to transfusion and only Rh-negative blood should be used in negative cases.

KALA-AZAR

Report of a Case Showing Unusual Leukocyte Response and Prolonged Incubation Period

CAPTAIN MOISE D. LEVY Jr.
Medical Corps, Army of the United States
and

FIRST LIEUTENANT MARVIN J. YIENGST
Sanitary Corps, Army of the United States

Prior to the onset of World War II, kala-azar (visceral leishmaniasis) was a disease discussed only by those few who specialized in tropical medicine and by members of teaching institutions when presenting cases of splenomegaly for differential diagnosis. In the latter instance, kala-azar was usually discarded as a possible diagnosis because the patient had never been out of the United States. Today this may not be true. During the recent war and continuing even to the present time several hundred thousand American troops were and are stationed in the several parts of the world where kala-azar is endemic, the most important of which are Eastern India, Burma, Northeastern China, Southern Italy and the Mediterranean coast of North Africa. Because of this and because the incubation period of the disease may be prolonged, the possibility of the occurrence of clinical kala-azar among former servicemen is more than theoretic.

Kala-azar is caused by the protozoan organism *Leishmania donovani*. It is agreed by most workers that the organism is transmitted to man by the bite of one of several species of the sandfly. On culture the organism develops in a flagellate form, while in man the organism appears as the Leishman-Donovan body. Strong¹ described this form as "round or oval bodies 2-5 microns in diameter. The nucleus is relatively large and peripherally placed; the kinetoplast is smaller, rod-shaped, or oval, and set at a tangent to the nucleus. A short, slender filament, the axoneme, is sometimes seen extending from the blepharoplast to the periphery. In a Romanowsky stain, the cytoplasm is faintly blue, the nucleus appears as a mass of bright red granules, and the kinetoplast is deep reddish purple."

Clinically there is no typical picture. The fever may be alternating, remittent or intermittent. In some cases, however, there is a double or triple daily rise in the temperature, which is said to strongly suggest the diagnosis of kala-azar. It has also been observed in this disease that a patient may have a temperature of as much as 102 F. and state that he feels well. The onset of the disease may be sudden with high temperature, chills and vomiting, or it may begin gradually with a low grade fever and relatively mild general symptoms. The onset may be easily confused with typhoid or malaria, more particularly the latter, as malaria is endemic in many of the areas where one may become infected with kala-azar. The incubation period varies from ten days to eighteen months. The disease produces progressive loss of weight with noticeable wasting of the muscles. Enlargement of the spleen does not usually occur until after the first month of the disease.

From the Army Air Forces Regional Station Hospital, San Antonio, Texas.

NOTE: The Department of Pathology, Baylor University School of Medicine, assisted in obtaining the photomicrograph of the bone marrow specimen in this case.

1. Strong, R. P.: *Stitt's Diagnosis, Prevention and Treatment of Tropical Diseases*, ed. 7, Philadelphia, The Blakiston Company, 1944, vol. 1, pp. 229-319.

The hemogram is said to offer some aid in the diagnosis of kala-azar. There is anemia present, usually becoming evident after the first month of the disease. The most dramatic changes occur in the white cell count. The total number of white blood cells is greatly reduced—in the majority of cases to less than 3,000 per cubic millimeter. The differential picture reveals a reduction in the polymorphonuclear leukocytes and an increase in the number of the large mononuclear cells and lymphocytes. However, in the case to be reported there was a decided shift to the left in the differential count. Another important finding is the alteration in the ratio of the white blood cells to the red blood cells. The normal ratio of 1:666 or 1:750 is only rarely observed. In cases of kala-azar the ratio of these cells is usually in the range of 1:1,000 or 1:1,500.

Blood chemical studies reveal an elevation of the globulin fraction of the blood serum. The euglobulin fraction is often considerably elevated and may account for 40 to 50 per cent of the total globulin. The formaldehyde gel test is positive in result in cases of well established kala-azar and gradually reverts to normal as recovery ensues. A similar reaction with a

oxalate, and after the cells have been spun down, the buffy layer of leukocytes may be inoculated on the mediums. In culture the parasite develops in the flagellate form. It has been suggested that culture be attempted in any case in which the diagnosis is suspected.³

Several pentavalent antimony compounds are available for the treatment of kala-azar. Many workers prefer ethylstibamine, as it is reported to be less toxic than other drugs and its therapeutic efficiency is high. This drug may be given intravenously or intramuscularly, the intravenous route being preferred. The first dose should be 0.1 or 0.2 Gm., being increased to 0.3 Gm. as a maintenance dose. The injections may be given daily or less often, depending on the reaction of the patient. Total dosage recommended varies from 3.5 Gm. to 5 Gm. The larger figure may be exceeded in cases in which the disease is more resistant to treatment. The drug is relatively safe, but certain reactions may be observed, the most common of which are nausea and vomiting that occur shortly after the injection. If the patient remains at complete bed rest and does not eat for one to two hours after the injection.

pentavalent antimony compound such as ethylstibamine ("neostibosan") may give additional presumptive evidence for the diagnosis of kala-azar.

There is only one means for the positive diagnosis of this disease and that is to demonstrate the causative organism in tissue taken from the patient. In the vast majority of patients this is simply and easily done if the possibility of such a diagnosis is kept in mind and searched for. The most simple and least dangerous procedure is needle aspiration of the sternal bone marrow. This technic is practically devoid of danger and if properly done will demonstrate the parasites in a high percentage of cases. An alternative to this procedure is the surgical biopsy of the sternum, the specimen of marrow being obtained after the sternum has been trephined. Splenic puncture is generally conceded to give the highest number of positive smears, but this technic presents definite hazard to the patient, and, in cases in which the spleen is not palpably enlarged, it is almost impossible to perform. Meleney² stated that aspiration of the liver demonstrates the organisms in a high percentage of cases and claimed that the procedure is not unduly dangerous if carefully and properly performed. Demonstration of the parasites in the peripheral blood is reported but is infrequent. Culture of the organisms on Nicolle, Novy and McNeal mediums may be done, material obtained by any of the procedures mentioned being used. Also a specimen of blood may be obtained under sterile technic in

these symptoms will often be minimized. If vomiting persists, smaller doses of the drug should be given. Symptoms resembling anaphylactic shock have been reported, usually after several injections have been given. Urticarial rash, laryngeal edema, cyanosis and signs of asthma may develop. Epinephrine will relieve these symptoms, but since these symptoms, which may result after the use of any of the antimony compounds, will often recur when that particular drug is again administered, it has been suggested that a different antimony compound be used to complete the treatment.

REPORT OF A CASE

A pilot officer, aged 25, was admitted to the hospital on Sept. 21, 1946. Symptoms began September 7 with mild generalized malaise and mild intermittent pain in the left upper part of the abdomen. His appetite decreased and he noted increasing fatigue. He reported to his station dispensary on September 16 because of the progression of these symptoms. Acetylsalicylic acid, acetophenetidin and caffeine tablets were prescribed. On September 18 a roentgenogram of the chest was reported normal. The morning of September 19 the patient felt somewhat improved, but that afternoon he noted a cold tingling sensation in his hands, and shortly thereafter a chill developed, after which his oral temperature was 104 F. Without laboratory studies the patient was treated with quinacrine, 0.1 Gm. three times daily. At about 2 a. m., September 20, he had a second chill followed by vomiting. The vomitus consisted of the food eaten at the previous evening meal. He had two diarrhea stools and there were repeated chills approximately every six hours

3. Packchianian, A.: Leishmaniasis: Cultivation of Leishmania Tropica from Two American Soldiers Who Had Returned to the United States from Near East, J. A. M. A. 129: 544-547 (Oct. 20) 1945.

until the morning of September 21, when he again reported to his dispensary. Oral temperature at this time was 101 F., and he was then hospitalized with a presumptive diagnosis of malaria. There had been weight loss of 20 pounds (9.1 Kg.) in the two weeks prior to hospitalization.

Past History.—He had experienced no similar symptoms prior to the onset of the present illness. He served overseas as a fighter pilot in the China-Burma-India theater from December 1943 to April 1945. There was no history of previous attacks of malaria. He experienced one episode of diarrhea lasting one week in May 1944 while stationed in India. No specific etiologic agent was found, and the diarrhea responded to nonspecific treatment.

Examination.—The patient was acutely ill and somewhat emaciated, and showed recent loss of weight. There was a slight injection of the membrane of the throat and a mild gingivitis was present. There was no nuchal rigidity; no evidence of superficial lymphadenopathy, rash or petechial eruption. The heart was normal, and the lungs completely clear. Blood pressure was 110 systolic and 64 diastolic. The abdomen was soft and flat, and neither the liver nor the spleen was palpated. No abdominal masses were evident. There was slight tenderness on deep palpation in the left upper part of the abdomen. The remainder of the physical examination revealed no abnormalities.

Quinacrine was continued, 0.1 Gm. three times a day, in spite of a negative malaria smear, because it was felt that the low initial dosage given this patient may have cleared the parasitemia and yet have been insufficient to cause a remission of clinical symptoms. On September 23 there was a total white blood cell count of 1,800 with 29 per cent lymphocytes, 2 per cent monocytes, 13 per cent segmented polymorphonuclear cells, 25 per cent band forms, 28 per cent juveniles and 3 per cent myelocytes. On this date a second study for malaria failed to reveal the presence of parasites. Because of this and because the blood picture indicated possible leukemia and/or severe infection as yet undiagnosed, quinacrine was discontinued; penicillin, 50,000 units intramuscularly every three hours, and liver extract, 3 cc. daily, were administered. Blood counts continued to show profound leukopenia with a considerable shift to the left in the differential picture. There was only mild anemia noted at any time. The table shows the data on the blood during the entire period. Repeated examinations of the urine, including a test for Bence-Jones protein, revealed no abnormality. An aspiration biopsy of sternal bone marrow was made on September 25, and stained smears revealed a normal differential cell count. No organisms were seen in the five slides examined. A platelet count on September 26 was 111,800 (normal 250,000 to 500,000). The patient's temperature continued on a septic course (fig. 1). Many blood cultures remained sterile after prolonged incubation. An organism having the carbohydrate reaction of *Salmonella eastbourne* was isolated from the stool on two occasions. Agglutinations for typhoid, paratyphoid, undulant fever and heterophil antibody were negative on September 24 and September 30. On the latter date the Weil-Felix reaction and agglutination with *Pasteurella tularensis* were also negative. On October 2, roentgenograms of the chest and abdomen were normal—there was no evidence of enlargement of the spleen or liver. On October 3, a biopsy specimen from the upper part of the sternum was obtained by trephine. Several impression smears were made from the marrow, and after staining with a diluted Giemsa stain, examination revealed many intracellular and extracellular organisms which were typical of the Leishman-Donovan bodies of kala-azar (fig. 2). Treatment with ethylstilbamidine was begun on October 5, the patient receiving 0.2 Gm. intravenously on this date. Daily thereafter, through October 20, he received 0.3 Gm. intravenously. A total of 4.7 Gm. was given; no adverse effects were observed.

Response to treatment was dramatic; the temperature returned to normal after three days, appetite greatly improved—four meals daily were enjoyed—and there was a progressive gain in weight from 130 pounds (59 Kg.) to 152 pounds (68.9 Kg.). The table shows the improvement in the peripheral blood. Penicillin was continued until October 5, as a precaution against secondary infection. Attempts to culture marrow blood and

peripheral blood on mediums developed by Nicolle, Novy and McNeal were unsuccessful. On December 3 the patient was returned to duty; no evidence of disease was present. He was, however, instructed as to the symptoms and signs of relapse of the disease and warned of the possible late occurrence of post-kala-azar cutaneous leishmaniasis.

COMMENT

After the correct diagnosis was made in this case, a more complete history of the specific areas visited during the patient's tour of overseas duty was obtained in an attempt to estimate the incubation period. He was in several areas in which kala-azar is known to be endemic. In May 1944 he was located on the south-east coast of India near the Burma border. From November 1944 until February 1945 he was in the vicinity of Sien, China. This town is located just south of the bend of the Yellow River and is within the area of China where this disease is endemic. While returning to the United States via air transport the patient spent one day each in Abadan, Iran, and Cairo, Egypt. These cities are both located in areas where cutaneous leishmaniasis is endemic and where an occasional case of the visceral disease is reported. It is our belief, because of the longer period of exposure while this officer was stationed in China, that his disease was most likely contracted some time between November 1944 and February 1945. On this supposition, the

Fig. 1.—Temperature chart showing double and triple daily elevations. The temperature was determined at 12, 4 and 8 a. m., and 12, 4 and 8 p. m. (from left to right in each column). Treatment with ethylstilbamidine started on October 5.

incubation period in this case was at least nineteen months, if it is assumed that the patient became infected only shortly before he left this area. The patient was in Abadan on April 1, 1945 and in Cairo on April 2, 1945. He arrived in Casablanca in the western part of North Africa on April 3, 1945 and left this area by air on April 10, 1945, arriving in the United States on April 11, 1945. If the time from April 10, 1945, when the patient left the African continent and any possible source of infection, until the onset of symptoms on Sept. 7, 1946 is considered, an incubation period of approximately seventeen months is indicated. The prolonged period of incubation in this case is unusual, and we have been able to find only 1 such case previously reported.⁴

The possibility of prolonged periods of incubation in kala-azar serves to emphasize the importance of this disease in the United States. It must be strongly considered in cases of obscure fever in persons who have spent time in areas where kala-azar is endemic.

The second unusual feature of the case presented in this report is the considerable shift to the left observed in the differential white cell count. It is reported that this disease produces a relative lymphocytosis.⁵ This was never observed in the case under discussion, and

4. Napier, cited by Strong.¹

5. Since preparation of this paper, two reports have appeared in which cases of kala-azar with similar blood pictures have been observed: Waud, S. P., and Kruger, S.: Visceral Leishmaniasis: Report of a Case, *New England J. Med.* 236: 63 (Jan. 9) 1947. Ecker, H. D., and Lubitz, J. M.: Kala-Azar in the United States: Review of the Literature and Report of Two Cases; Stilbamidine Treatment, *Ann. Int. Med.* 26: 720-733 (May) 1947.

there was no evidence at any time of other infection which might have explained the blood picture observed.

The one typical finding in this case was the temperature course. It is said that two or three spikes in the temperature every twenty-four hours is only rarely observed in diseases other than kala-azar. Figure 1 clearly shows this finding on several days.

SUMMARY

A brief review of kala-azar is presented, showing its symptoms, signs, methods of laboratory diagnosis and treatment. An unusual case of kala-azar with an incubation period of at least seventeen to eighteen months and with unusual hematologic observations is reported. It is believed that this case will help to emphasize the fact that kala-azar is now a disease which must be considered in the differential diagnosis of fevers

Fig. 2.—Photograph of bone marrow showing intracellular Leishman-Donovan bodies.

which may occur in patients living in the United States who give a history of spending time in any of the areas of the world where this disease is endemic.

Smallpox Vaccination and Encephalitis.—It is well known that encephalitis occasionally follows vaccination. When it is due to vaccination, it almost invariably occurs eleven to fourteen days later. It may occur up to thirty days later, but this is exceedingly rare. From the beginning of April, when the vaccination program was instituted, until the second week of June, 50 possible cases of encephalitis were reported to the Health Department. Four of these cases were ruled out as definitely not encephalitis. In the remaining 46 cases the diagnosis was considered probable. Eight of these 46 individuals died. A diagnosis of postvaccinal encephalitis can be made with certainty only after microscopic examination of the brain tissue. Brain tissue of the 8 fatal cases was examined, and in none of them were the characteristic lesions of postvaccinal encephalitis found. Autopsy showed that 2 of the deaths were caused by tuberculous meningitis, 1 by a brain tumor, 1 by coronary sclerosis, and 4 probably by cerebral lesions. The Health Department has had no proof of any death due to postvaccinal encephalitis in its vaccination campaign.—Weinstein, Israel, M.D., An Outbreak of Smallpox in New York City, *American Journal of Public Health*, November, 1947.

STREPTOMYCIN IN THE THERAPY OF GRANULOMA INGUINALE

and

R. B. DIENST, Ph.D.

Augusta, Ga.

Streptomycin has been found to be active principally against certain gram-negative organisms and acid-fast bacilli. Its trial in the management of granuloma inguinale, while not entirely justified in view of the controversial concept of the nature of the pathogenic agent, was warranted on the basis that the need for a more effective and specific form of therapy of granuloma inguinale was greatly desired. Before the advent of the antibiotics the modern therapy of granuloma inguinale generally involved the use of one of a number of antimony compounds. These have varied from the intravenous injection of such antimonials as antimony potassium tartrate and "diramin" (an aqueous solution of the products resulting from the reaction between antimony catechol and triisopropanolamine in the presence of propylene glycol) to the intramuscular administration of the less toxic and more stable derivatives, such as lithium antimony thiomalate ("anthiomaline") and stibophen.¹

In addition, adjuncts to antimony therapy have been advocated and appear to accelerate healing. These have included local application of various preparations such as oxidizing agents (potassium permanganate washes) or spirocheticidal substances as 10 per cent neosarsphenamine in equal parts of cod liver oil and glycerine.^{1a} Other therapeutic measures have included the use of 20 per cent resin of podophyllum in olive oil applied for its escharotic activity on the granulation tissue, followed in turn by an epithelial stimulant such as scarlet red.² These additive measures, together with surgical treatment and irradiation, have often been necessary in the form of supplementary treatment to control the superimposed infection. The effectiveness of the employed therapeutic regimens when used either alone or in conjunction with one another decreases in direct proportion to the longevity of the lesion. The early lesions of granuloma inguinale respond well to therapy, and in rare instances ordinary hygienic measures may bring about a spontaneous cure.

It must be admitted that the antimonials will cause a regression and will result in abeyance of the disease in many patients with granuloma inguinale. However, a more rapid and propitious form of therapy was sought. The introduction of the various antibiotics led to their eventual trial in the management of this minor venereal disease. Thus, 1,000,000 to 2,000,000 units of penicillin has been administered to patients with no discernible benefit.^{3c} Similar observations on the

refractoriness of granuloma inguinale to penicillin have been reported in the literature.³ In contradistinction to the clinical observations with penicillin, *in vitro* studies have shown that penicillin in high concentrations was not without effect on the Donovan body.⁴ It has also been shown that the local application of tyrothricin to the exuberant tissue characterizing many lesions of this disease failed to exert any appreciable therapeutic effect.⁵ However, the eventual trial of streptomycin in contrast to the foregoing antibiotics has yielded the most promising outlook for the control of granuloma inguinale. Observations on the use and effectiveness of streptomycin in the treatment of granuloma inguinale have been presented in a preliminary report.⁶ In this paper our observations on streptomycin are extended and a more detailed description of the cases is presented.

PATIENTS

A total of 48 patients have received streptomycin for granuloma inguinale. There was a total of 32 male and 16 female patients, all Negroes and ranging in age from 19 to 70 years. Of these 48 patients, 35 had received some form of antimony therapy for periods of time varying from one month to ten years. Most of these patients had received inadequate treatment at sporadic intervals. Some reported cures or disappearance of the lesion for short periods of time following antimony therapy. However, despite the duration of previous treatment with antimony compounds, Donovan bodies were demonstrated either by spread or biopsy section from the lesions of all patients before initiation of streptomycin therapy. The remaining patients who had not received previous antimony treatment had been given other forms of therapy such as penicillin, arsenic, or one or another of the sulfonamide drugs because of faulty diagnosis.

DOSAGE

The dosage of streptomycin employed ranged from 3.3 Gm. to 60 Gm. with an average dose of 20 Gm. The drug was given in amounts varying from 0.3 Gm. to 4 Gm. per day in divided doses every four hours for a period ranging from five to sixty-two days. The drug was dissolved in sterile distilled water containing 25 to 30 per cent of 1 per cent solution of procaine hydrochloride. In the earlier stages of this study the dose was judged empirically and was based on the extent and duration of the lesion. However, the present plan has entailed the administration of 4 Gm. of streptomycin per day for a period of five days. The purpose of this mode of therapy was twofold in nature: (1) to provide for a rapid and effective method of treatment and (2) to administer high doses and maintain high levels of streptomycin in the patient, thereby preventing the development of organisms resistant or refractory to the antibiotic.

TOXIC EFFECTS

Toxic reactions were noticed in 4 patients receiving daily doses of 1 to 4 Gm. of streptomycin. However, in no case was involvement of the eighth nerve observed. Pruritus was observed in all 4 cases, and in 1 patient this was associated with an urticarial eruption on the

chest and extremities and a vesicular perioral dermatitis. Fifty milligrams of diphenhydramine hydrochloride, given twice a day, effectively controlled the pruritus in the 3 patients without the dermatitis, thereby permitting continuation of the streptomycin therapy. However, the patient exhibiting the dermatitis failed to respond to the same dose of diphenhydramine hydrochloride, and streptomycin therapy was advisedly discontinued. A fifth patient complained of a mild burning of the conjunctiva after having received a total dose of 3 Gm. of streptomycin over a ten day period. Administration of the drug was discontinued for four days, and with resumption of the same dose no untoward symptoms were noticed.

RESPONSE AND CLINICAL EFFECT

Frequent smears were taken from the lesions of the patients receiving streptomycin throughout the course of treatment. Negative smears were obtained within two to eleven days, or an average of six days (in 26 patients), after initiation of the streptomycin injections. However, the lesions clinically still showed evidence of granulation tissue. Microscopically it was observed that the streptomycin apparently caused disintegration of the Donovan bodies. On the other hand, we have frequently observed well preserved Donovan

bodies in smears of the lesions in patients who have received stibophen two times weekly for several months. Donovan bodies were observed in the lesions of these patients despite the evidence of decided clinical improvement. The significance of these observations will be discussed later, and a more detailed account will be presented elsewhere in a report devoted to bacteriologic aspects of this problem. The patients treated with 0.3 to 1 Gm. of streptomycin per day were maintained on the antibiotic until few or no residual lesions were observed. However, the patients treated for five days with 4.0 Gm. of the drug per day still showed granulomatous lesions at the time that the streptomycin therapy was discontinued. Nevertheless, despite the lack of additional therapy, the lesions in these patients eventually showed complete healing, eight to twelve days after cessation of treatment. All the patients, especially those with extensive lesions, volunteered the information that within twenty-four to thirty-six hours after initiation of streptomycin therapy the pain or discomfort associated with the lesion was markedly reduced or absent. Some healing of the lesions was noted within twenty-four to forty-eight hours after the antibiotic had been administered. Healing was, at first, centripetal in nature.

RELAPSES

Since the inception of this study has been of relatively recent origin the follow-up studies have been, of necessity, short in duration. To date there have been three

recurrences after therapy had been discontinued. Two of these patients had received less than 4 Gm. and 1 had received a total dose of 28 Gm. The lesion of this latter patient was almost completely healed, and after dismissal further healing occurred. However, there was a recrudescence of the lesion three

Fig. 1 (J. A.).—Granuloma inguinale of six years' duration in the genital area of patient. Note general destruction of genitalia by extensive granulation tissue.

months later. A second course of streptomycin therapy (1.5 Gm. per day for forty-one days followed by 4 Gm. per day for nine days or a total dose of 94 Gm. of streptomycin) was administered over a period of fifty

Fig. 2 (J. A.).—Granulomatous involvement of medial portion of left thigh and perianal area by extension of granuloma inguinale from the genital region.

days. Since no further progress toward healing occurred, it was concluded that the disease had become refractory to the antibiotic. Lithium antimony thiomalate therapy was then instituted in doses of 3 cc. injected intramuscularly six times a week for four weeks. Complete healing occurred with a total dose

of 72 cc. Follow-up studies in the patient are still in progress. She is to receive 3 cc. of lithium antimony thiomalate twice weekly for the next few months to prevent any further recurrence. Of the other 2 patients showing relapses after an initial course of therapy of less than 4 Gm. of streptomycin, recrudescence of the disease was noted within eight weeks after discontinuing the injection of the antibiotic. One patient received an additional course of treatment consisting of 4 Gm. of streptomycin per day given for eleven days. The lesion healed completely and there has been no evidence of a recurrence five weeks later. The other patient was also placed on 4 Gm. of streptomycin per day for eight days. Healing has occurred and the patient is now under observation.

REPORT OF CASES

CASE 1.—J. A., a Negro man 31 years of age, first noticed a lesion on the glans penis in 1941, six years before the present admission. The patient received a course of intravenous injection

Fig. 3 (J. A.).—Healed genital area three weeks after cessation of streptomycin therapy (cf. fig. 1).

tions at this time and some healing occurred. However, with further treatment the lesion continued to spread and heal alternately, so that eventually as a result of scar formation the penis was completely retracted and could not be recognized. Soon after the appearance of the penile lesion a pustule appeared in the suprapubic area. This area ulcerated and coalesced with the penile lesion to involve the genital region, medial aspect of the left thigh and the perineum. Despite intermittent antimony, arsenic and bismuth therapy the lesions slowly spread to their present proportions.

Examination showed a well developed poorly nourished Negro in apparent distress who could stand in the erect posture only with difficulty. A foul, acrid odor was associated with an extensive granulomatous lesion in the genital area (fig. 1). The lesions were extensive and characterized by a moderately proliferated red granulating base covered with a weeping, serosanguinous grayish exudate. There were no visible external genitalia, and the urinary meatus was camouflaged by the surrounding ulcerated area and could not be identified. The lesion involved the suprapubic area and left inguinal region, and extended down the medial aspect of the thigh to the perineum and perianal area (fig. 2). Smears made from the

lesions showed numerous Donovan bodies. The penis and scrotum while not apparent were covered by the granulation tissue (fig. 1). The patient was placed on 1 Gm. of streptomycin per day, administered in divided doses at four hour intervals. Smears made on subsequent days showed Donovan bodies in the lesion to be present only for the first five days

Fig. 4 (J. A.).—Healed perianal and perineal lesion observed after cessation of streptomycin therapy (cf. fig. 2).

of streptomycin therapy. Thereafter negative smears were obtained. The pain associated with the lesion was markedly reduced after the first day of treatment and completely absent after forty-eight hours. The patient received a total dose of 21 Gm. of streptomycin. At the time that the injections were discontinued small areas of granulation tissue were present. These were completely healed three weeks after cessation of streptomycin therapy (figs. 3 and 4). No recurrence has been observed sixteen weeks after treatment. After the streptomycin therapy had been discontinued the urinary meatus could then be seen in the healed area between the medial left thigh and inferior lateral portion of the infrapubic area (fig. 3). Future plastic surgery has been advised for repair and proper presentation of the penis and scrotum.

CASE 2.—L. M. F., a Negro woman 26 years of age, was admitted to the granuloma ward because of extensive lesions and scar formation of the pubic and perineal area. The initial lesion was noticed six years ago in the left inguinal region. The lesion spread from this area to the suprapubic region and by retrograde extension to the vulva and perineum. These areas were all at one time involved with the granulomatous lesion characterizing the patient's disease. She had received intermittent antimony therapy at different clinics over the last six years and, while improvement of the lesion was noticed, complete healing never was attained.

Examination showed a well developed and well nourished Negro woman exhibiting extensive scar formation and depigmentation in the inguinal and genital region. Granulation tissue was observed in one small lesion in the right suprapubic region extending down on the right labium majus to the perineum and perianal area with some extension up the inferior part of the left labium majus. There was marked depigmentation of both labia associated with elephantiasic enlargement of a brawny indurated nature. Smears made from the lesion showed numerous Donovan bodies to be present. The patient was placed on 0.3 Gm. of streptomycin per day for twenty-six days, or a total dose of 7.8 Gm. Healing was apparent after 2 Gm. had been administered. Complete healing was present

when the patient had received the total dose. Follow-up study of ten weeks has shown no recurrence.

CASE 3.—R. A., a Negro man 22 years of age, had noticed a small nodular swelling of the glans penis five years prior to his present admission. This lesion ulcerated and gradually involved the entire glans and the distal portion of the shaft. Soon after the development of the penile lesion similar ulcers appeared first in the right and then in the left inguinal region. The ulcerated areas became confluent by direct extension and spread inferiorly to the perineum and perianal area so that at one time the genital, inguinal and perianal area were one beefy red mass of granulation tissue. In addition, circular contact lesions developed on the medial aspect of each thigh. Soon after the beginning of the penile ulcers the patient was placed on antimony potassium tartrate, and finally stibophen was administered intermittently from 1942 to the present date. The antimony therapy induced sporadic healing in some sites with resulting scar and keloid formation. However, at no time were all lesions completely healed.

Examination revealed a well developed, poorly nourished Negro man in apparent distress and emitting a foul, pungent odor. There were extensive keloid formation and depigmentation in both the inguinal and pubic regions. The penis could not be recognized and was represented by a small tuft of granulomatous tissue pointing toward the left thigh. A linear mass of granulation tissue extended from the left inguinal region to the perineum. A circular contact granulomatous lesion was present on the medial aspect of the left thigh in an area where healing had previously occurred (fig. 5). There was also an area of granulation tissue on the right side between thigh and scrotum (fig. 5). The scrotum was completely retracted by keloid formation and the testis was pressed against the external abdominal ring. The ulcerated areas showed the typical granulomatous lesions characterizing granuloma inguinale. There was a small amount of superficial exudate on the typical

Fig. 5 (R. A.).—Active granuloma inguinale infection of genital area associated with erosion of penis.

beefy red granular base. Numerous Donovan bodies were demonstrated in spreads from the lesions. The patient was placed on 4 Gm. of streptomycin per day for a total dose of 20 Gm. The pain associated with the lesion was alleviated within twenty-four hours after the streptomycin injections had been initiated. Healing was evident within forty-eight hours and Donovan bodies could not be demonstrated in spreads made

from the lesion after the patient had received 16 Gm. of streptomycin over a four day interval. After cessation of injections appreciable granulation tissue was still evident. However, three weeks later complete healing had occurred, with only a small area of granulation tissue present at the region of the external urinary meatus (fig. 6).

CONCLUSIONS

1. Streptomycin was employed in the management of 48 cases of granuloma inguinale in doses ranging from 3.3 to 60 Gm., administered over a period of time ranging from five to sixty-two days. Healing occurred in all patients, either while the antibiotic was being administered or after cessation of therapy.

An average follow-up study of nine weeks has shown that the disease recurred in 3 patients; of these, 2 responded to a second course of therapy. In the third patient resistance to the drug developed; she was placed on an organic antimony compound. Some patients

Fig. 6 (R. A.).—Healed lesion seen three weeks after cessation of streptomycin therapy (cf. fig. 5).

have shown no recrudescence of the lesions four to five months after cessation of therapy.

A five day treatment schedule has been evolved. This is based on the administration of 4 Gm. of streptomycin per day or a total dose of 20 Gm. of the antibiotic over the five day period. Lesions were present after this therapy had been discontinued, but complete healing occurred within the next one to four weeks despite the fact that no additional drug was given.

The only toxic effects noted after administration of streptomycin were pruritus (4 cases) and urticarial dermatitis (1 case). No involvement of the eighth nerve was observed. The pruritus was controlled in 3 patients by the administration of diphenhydramine hydrochloride.

It is concluded that streptomycin gives promise of being the most effective drug in the control of granuloma inguinale and that only longer post-treatment periods of observation are necessary to establish this contention.

ADDENDUM

Since the presentation of this paper, an additional 43 patients have been treated with streptomycin, bringing the total to 91 cases. Analyses of the results of the complete series now show that of the 32 patients who received 2 Gm. per day or less of streptomycin over a period averaging twenty days there were 8 recurrences, 7 of which were retreated, with successful results in 5. The remaining 2 have become streptomycin resistant. Of the 51 patients treated with 4 Gm. per day for five days, there has been 1 recurrence which healed with retreatment. Seven patients received 4 Gm. per day for more than five days, i. e., six to ten days, with no relapses thus far. One patient was treated with streptomycin vaginal suppositories alone, 4 Gm. per day for four days, with complete healing. From our data, it appears that the administration of 4 Gm. of the drug per day for five days is the most satisfactory as well as the most economical method of treatment.

ABSTRACT OF DISCUSSION

DR. ROBERT R. KIERLAND, Rochester, Minn.: The results obtained by the authors are far superior to those obtained by any previous method of therapy available for this chronic and disabling disease. So outstanding are their figures that one may be tempted to use streptomycin as a "therapeutic trial" in cases of unproved but strongly suspected granuloma inguinale. These findings confirm or are confirmed by the independent investigation made by Barton and his associates (Barton, R. L.; Craig, R. M.; Schwemlein, G. X., and Bauer, T. J.: *Granuloma Inguinale Treated with Streptomycin: Report of Three Cases*, unpublished data) at the Chicago Intensive Treatment Center, the results of which were submitted for publication in September 1946. Their original series comprised 3 patients but they have since added more. The first 3 patients with proved granuloma inguinale received 20,000 to 30,000 units of streptomycin every three hours until a total dosage of 4,000,000 to 7,000,000 units had been received. There was evidence of rapid clinical improvement, while Donovan bodies could not be found in scrapings of tissue as early as ten days after treatment. Relapses occurred in 2 of these patients. Later, however, in 7 additional patients (Marshak, L. C.; Barton, R. L., and Bauer, T. J.: *Granuloma Inguinale: A Report of the Literature and a Report of Ninety-Seven Cases with a Note on Streptomycin Therapy*, unpublished data), the dose per injection was increased to 50,000 units and a total dosage of 6,000,000 to 10,000,000 units was given with no relapse as long as six months after treatment. It is entirely possible that the use of large doses of 4 Gm. daily for five days, advocated by the present authors, has added materially to the small incidence of relapse. The factors of optimal dosage, duration of treatment and the combination of streptomycin with other therapeutic agents will undoubtedly be determined in the future. The relative purity of streptomycin is a matter that has received much discussion as far as reactions are concerned. As purer forms of the drug are obtained the incidence of cutaneous reactions may be lowered. The appearance of the more serious toxic manifestations, such as nerve deafness and loss of labyrinthine function, may be due to the drug itself and is an indication for discontinuance of the drug. That this will be unusual is indicated by the fact that no serious toxic reaction occurred in this series of 48 cases. The original demonstration of the culture and propagation of *Donovania granulomatis* by Anderson and more recently by others leads the way for the *in vitro* investigation of streptomycin and other antibiotic substances.

DR. DONALD M. PILLSBURY, Philadelphia: This is the type of paper on which discussion is a pleasure, because the authors are competent observers, have maintained adequate and expert laboratory controls on the clinical diagnosis, report a significant

number of patients treated and are conservative in their statements of the results obtained. There seems no question that streptomycin in moderate doses has a strikingly favorable effect on the lesions of granuloma inguinale in most patients with this disease. Moreover, although the average time of follow-up observation in the authors' 48 patients is only nine weeks, it seems most probable that a majority of those treated have been cured. Certainly the results achieved are much superior even to those obtained with intensive daily stibophen therapy. Any one who has been associated for some years with a large clinic for venereal or dermatologic diseases inevitably comes to the conclusion that granuloma inguinale is one of the worst treated of all the diseases affecting the skin and subcutaneous tissues. The unfortunate patients with this disease are ordinarily not blessed with even average intelligence, and continuous treatment and adequate follow-up of them are difficult to accomplish. Furthermore, the lesions of the disease lack esthetic appeal to say the least, and few physicians and nurses will carry out the necessary diagnostic and local procedures with any enthusiasm. As a result, one regularly sees patients who have had intermittent treatment and who have drifted from one clinic to another, with increasing disability, mutilation and discomfort from the disease. Streptomycin therapy offers hope that most of these patients can be cured within a short period of treatment. Fortunately, the amounts of streptomycin which seem necessary are not of an order likely to produce a high incidence of serious reactions. The calculated risk is well justified. It must be kept in mind that streptomycin when administered over periods of weeks to months, is capable of producing severe reactions and permanent disability. In a study recently completed under the auspices of the Streptomycin Committee of the Veterans' Administration, and in other studies, it has been found that streptomycin may have definite toxic effects on the vestibular and/or acoustic portions of the eighth nerve, with a possibility of total deafness if the drug is continued, may produce irreversible renal damage, rarely may produce dermatitis reactions of the ninth day erythema type and, also rarely, may have dangerous effects on bone marrow function.

DR. HAROLD L. HIRSH, Washington, D. C.: Early this year we learned about the work of Dr. Kupperman and his associates and consequently undertook a study of the treatment of granuloma inguinale with streptomycin. We have completed the treatment of 17 patients. We used a total of 1 Gm. a day given intramuscularly in divided doses every four hours. Our results are almost identical with those reported by Dr. Kupperman and his associates. We, too, noted that within twenty-four or forty-eight hours there was marked relief in the pain from the lesions. Particularly the female patients who previously refused to allow examination were quite willing to be examined. Furthermore, the lesions which had previously been red and raw and angry in appearance became less intense, purplish in color and showed evidence of healing. In about a week, it was evident that the lesions were healing in a centripetal fashion. Although some of these patients had extensive granulomatous masses, at about the end of a week the masses began to shrink in size and the shrinkage continued even after treatment was discontinued. In several patients we contemplated removing these extensive granulomatous masses after treatment was completed. This was done on only 1 male patient for the purpose of examining the residual tissue more completely. We only did weekly smears and found that in every patient the Donovan bodies were present at the end of one week; in the second week specimens they were completely gone. The duration of treatment in our patients has ranged from eight to forty-seven days. We continued treatment until the ulcerative lesions were completely healed. The follow-up period has now been for periods up to ten weeks for some patients. We noticed that in patients who had moist ulcerative lesions that were in apposition or that were bathed by vaginal discharge the healing was somewhat slower. We had several complications in our

series. One patient was delivered of a viable infant at seven months, ten days after treatment was started. Another patient was six months pregnant when treatment was started and at the conclusion of treatment her pregnancy had apparently progressed uneventfully. Another patient had secondary syphilis which was treated with penicillin concurrently with apparently good results. Another interesting problem was that 1 of the patients with a granulomatous lesion of the groin had a remarkable response for the first ten days, but thereafter there was no further improvement. We went back and studied the original and follow-up slides and found that he also had a squamous cell carcinoma at the site of the venereal disease. We think that the effect of streptomycin in granuloma inguinale is remarkable.

DR. HARRY M. ROBINSON, Baltimore, Md.: It would be a great satisfaction to get a good result in some of those poor suffering Negroes who in the vast majority of instances have no money and no facilities for treatment and for whom hospitalization is practically impossible to obtain. I did not hear whether the investigators made any biopsies from the scars. In some of those patients whom we treated with other methods, in doing biopsies on scars we found cells including Donovan bodies. We were able to control granuloma inguinale to a certain extent with the antimony products when the condition was caught in the early stage, but when the treatment was stopped, later practically the entire condition recurred. In some of the patients on whom we worked with excision, while some of the scar following excision remained undisturbed, at the margin of the scar new granuloma inguinale tissue appeared. I certainly hope that this bears out the promise that it appears to have. I am not saying this in a questioning mood; it is just a marvelous possibility, and we hope to try it ourselves.

DR. R. B. GREENBLATT, Augusta, Ga.: Through the Public Health Service we were able to obtain supplies of streptomycin, and work on a series of cases was started in the early fall of last year. Of all the diseases which we see in the South, granuloma inguinale is one of the tragic illnesses. The wretched, poverty-stricken patients do poorly on ambulatory treatment with antimonials, and some cases have come to our attention in which foul, ulcerative wounds have been present for ten to twelve years. Dr. Kierland made mention of the Chicago group who last summer treated 3 cases. We are glad to hear about it and would like to concede priority to them. We did not know about their experimental work at the time that we made our contacts for work with streptomycin in granuloma inguinale. Dr. Pillsbury's remark that "we owe a debt to society in the treatment of patients with granuloma inguinale" is timely. We, too, feel that though these patients have to be hospitalized and though streptomycin is expensive we can at least offer them hope for rehabilitation and an opportunity to become decent members of society. Heretofore, I think the management of granuloma inguinale has been a blot on our public health escutcheon. The apathy shown by physicians in the care of these patients is regrettable. Dr. Hirsh, we are happy to learn, has been able to corroborate our findings on the use of streptomycin. We are pleased to hear that he has developed a medium in which streptomycin may be administered at daily intervals. In regard to Dr. Robinson's query on whether biopsies were obtained from scar tissue, I might say that in all patients in this series biopsies or smears were taken before therapy and for many weeks after therapy. In only 1 instance was a biopsy taken from a healed scar to see whether Donovan bodies were to be found deep in the tissues. In the sclerosing type of granuloma inguinale a presumably spontaneous healing takes place by scar tissue. However, the study of biopsy sections from these scars reveals the presence of Donovan bodies. After adequate streptomycin therapy Donovan bodies disappear rather rapidly, and though healing may take place comparatively slowly, the granulation tissue remains free from the Donovan body until healing is complete.

EFFECTS OF URETHANE IN THE TREATMENT OF LEUKEMIA AND METASTATIC MALIGNANT TUMORS

Milwaukee

The results in the treatment of chronic leukemia with urethane (ethyl carbamate), reported by Paterson, Haddow, ApThomas and Watkinson,¹ were sufficiently promising to stimulate further clinical investigation of this drug. We are presenting a report of our observations of the effect of urethane on leukemia and some of the malignant neoplastic diseases.

Urethane ($\text{H}_2\text{N.CO.O.C}_2\text{H}_5$) was first synthesized by Dumas² in 1834 from ethyl chloroformate and ammonia. White crystals are formed which are readily soluble in water and many of the commonly used organic solvents. It belongs to a group of organic esters of carbamic acid which are known collectively as urethanes because of their structural similarity to urea. The term "urethane" has been generally applied to ethyl carbamate itself. Carbamic acid is unstable and has not been isolated in the free state.

Although an extensive literature concerning urethane exists there are many gaps in our knowledge relative to its pharmacologic actions. Schmiedeberg³ studied its narcotic property in dogs and noted that with anesthetic and sublethal doses there was no significant effect on the pulse and respiration. Jolly⁴ was apparently the first to note the effectiveness of urethane as a hypnotic in clinical medicine. A number of other favorable publications appeared toward the end of the nineteenth century.⁵ The drug was popular for a brief period, but because of its weak and uncertain hypnotic action it was soon replaced by the more dependable barbiturates, then being introduced.

Haddow and Sexton⁶ have reviewed the experimental work leading up to the trial of urethane in the treatment of malignant growths and the incidental discovery that it was more effective in inducing remissions in human leukemia. Recent reports⁷ confirm the

effectiveness of the drug in mouse myelogenous and rat lymphatic leukemia. In this regard attention should be directed to the study of Hawkins and Murphy⁸ in 1925 on the effect of urethane in normal rabbits and rats. They found that urethane induced relative lymphocytopenia and granulocytosis, which they attributed to an accompanying uncompensated alkalosis. They obtained similar results by the injection of sodium bicarbonate or the administration of toxic doses of roentgen radiation. In addition they noted that rats under urethane anesthesia, given an exposure to roentgen rays well below the lethal dose, invariably died within seven to fourteen days.

Other effects reported with urethane include a decided antibacterial action,⁹ a significant antihistamine action which has been applied to the symptomatic treatment of bronchial asthma;¹⁰ hyperglycemia and glycosuria;¹¹ azotemia and increased urinary nitrogen excretion;¹² parasympatholytic effect;¹³ toxicity for rat liver,¹⁴ and carcinogenic action on mouse and rat lung¹⁵ and rat liver.^{16b} From its narcotic action it appears that the drug is rapidly absorbed from the gastrointestinal tract and rapidly eliminated from or altered in the body. That urethane is converted to urea and carbon dioxide in the body¹⁶ is no longer believed to be likely.¹⁷

METHOD OF ADMINISTRATION

Urethane was administered in several ways. Paterson and co-workers¹ prescribed the drug in a solution of chloroform water and syrup of orange. We have used 0.5 Gm. gelatin capsules and 0.5 Gm. enteric-coated capsules.¹⁸ Forty and 50 per cent solutions were used for intramuscular injection in some patients. Nausea was occasionally complained of soon after the nonenteric-coated capsules were ingested. We attribute this nausea to gastric irritation. Nausea with vomiting rarely developed after two or three weeks of oral therapy. This delayed nausea, which was prominent in case 15 during the third course of urethane, occurred after the dose had been doubled to 2 Gm. three times a day for ten days. Enteric-coated capsules were being given at this time. It is possible that this delayed nausea is a sign of overdosage. As much as 2 Gm. three times a day has been given intramuscularly without any complaint of local irritation. A hypnotic effect characterized by dizziness and drowsiness was fre-

quently noticed when urethane was given intramuscularly. A slight sedative effect was noticed by the patients taking 1 Gm. three times a day by mouth. We have not noticed any toxic effects other than nausea and occasional vomiting.

TREATMENT OF LEUKEMIA

The table is a summary of the essential clinical data obtained in the study of 25 patients with leukemia and lymphomatous diseases. It is noteworthy that the patients with acute and subacute leukemia died after

Summary of Essential Clinical Data in Twenty-Five Cases of Leukemia and Lymphomatous Diseases

Case No. and Patient	Sex	Age	Diagnosis	Acute and Subacute Leukemia			Tolerance of Urethane	Clinical Result
				Therapeutic Decrease in Leukocytes	Morphologic Changes of Blood	Decrease in Size of Spleen and Lymph Nodes		
1 L. J.	M	28	Acute lymphatic	30,800 to 750	10% reduction in lymphoblasts	Slight	1 Gm. t. i. d. oral capsules	Fair, slight nausea
2 A. S.	M	56	Acute lymphatic	7,300 to 550	Slight reduction in lymphoblasts	None	1 Gm. t. i. d. oral capsules	Fair, slight nausea
3 W. S.	M	57	Acute lymphatic	6,300 to 4,100; subsequently rose to 23,000	Slight reduction in lymphoblasts	Slight	1 Gm. t. i. d. oral capsules	Good
4 S. S.	M	64	Acute monocytic	8,700 to 2,600	No change	None	1 Gm. t. i. d. oral capsules	Good
5 C. T.	F	58	Acute myelogenous	71,000 to 6,400	Maturation noticed	Slight	1 to 2 Gm. t. i. d. oral capsules- roentgen therapy	Good
6 E. F.	M	37	Acute myelogenous	122,000 to 122,000	None	None	1 Gm. t. i. d. oral enteric-coated capsules and plain capsules	Good
7 G. R.	M	53	Subacute myelogenous	74,500 to 460	None	None	1 Gm. t. i. d. oral enteric-coated capsules; total dose only 12 Gm.	Good
8 B. S.	M	4	Subacute lymphatic	11,400 to 350	Almost complete reduction in lymphoblasts	Slight	0.25 Gm. daily to t. i. d., oral	Good
9 G. G.	F	44	Subacute lymphatic	157,200 to 16,000	None	None	1 Gm. t. i. d. oral capsules	Fair, nausea, loss of appetite
Chronic Lymphatic Leukemia								
10 W. G.	M	47	Chronic lymphatic	228,000 to 1,800	Blood and marrow smears now seem to be normal	Moderate	1 Gm. t. i. d. oral capsules; 90 r therapy	Good; slight nausea
11 M. V.	F	72	Chronic lymphatic	80,000 to 18,000	Decrease in lymphocytes	Slight	1 Gm. t. i. d. oral capsules	Poor; nausea
12 K. K.	M	60	Chronic lymphatic	20,000 to 80,000	None	Slight	1 to 2 Gm. t. i. d. oral capsules; 2 cc. 50% solution intramuscularly t. i. d.	Nausea; vomiting; dizzy after intramuscular therapy
13 S. S.	M	58	Chronic lymphatic	221,000 to 96,000	None	None	1 Gm. t. i. d. oral capsules	Fair
14 H. B.	M	53	Chronic lymphatic	76,000 to 20,000	None	None	1 Gm. t. i. d. oral capsules given for 84 days	Good
15 F. K.	M	57	Chronic lymphatic	188,000 to 55,000; 98,000	Slight reduction in lymphocytes	Moderate	1 Gm. t. i. d. plain oral capsules; then enteric-coated	Good
16 W. H.	M	51	Chronic lymphatic	120,000 to 90,400	Less smudge cells	Slight	1 Gm. t. i. d. plain oral capsules	Good
17 W. Q.	M	72	Leukosarcoma	22,000 to 15,100	Slight reduction in lymphocytes	Complete reduction in spleen and lymph nodes	2 cc. 50% solution intramuscularly; t. i. d.; later enteric-coated capsules	Good
18 J. W.	M	57	Chronic lymphatic	65,000 to 43,600	None	Very slight	1 Gm. plain capsules t. i. d. for 1 mo.	Good
Chronic Myelogenous Leukemia								
19 O. S.	M	57	Chronic myelogenous	310,000 to 3,400	Decrease in immature cells	Complete	1 to 2 Gm. t. i. d. plain and enteric-coated capsules; 2 to 4 cc. 50% solution intramuscularly	Good
20 P. H.	F	49	Chronic myelogenous	190,000 to 8,000	Decrease in immature cells	Complete	1 Gm. t. i. d. plain and enteric-coated capsules	Good
21 D. H.	M	68	Chronic myelogenous	125,000 to 8,200	Decrease in immature cells	Slight	1 Gm. t. i. d. plain capsules	Good
22 J. P.	M	57	Chronic myelogenous	57,000 to 20,000	Slight decrease in immature cells	No splenomegaly present	1 Gm. t. i. d. enteric-coated capsules	Good
Lymphomatous Diseases								
23 R. D.	M	39	Giant follicle lymphoma	13,600 to 7,600	None atypical lymphocytes	None	1 Gm. t. i. d. plain capsules	Slight nausea and anorexia
24 A. K.	F	39	Hodgkin's disease	13,600 to 8,950	None	None	1 Gm. t. i. d. plain capsules	Good
25 R. C.	M	28	Hodgkin's disease	6,000 to 1,000	None	None	1 Gm. t. i. d. plain capsules	Poor

a period of time comparable to that observed in patients treated by other therapeutic measures or without any treatment at all. Even though the number of leukocytes fell to severe leukopenic levels in most instances, the patients progressed along a more or less uninterrupted downhill course. In 2 of these patients, 7 and

Fig. 1.—Clinical course in case 7 (subacute myelogenous leukemia and leukemia cutis).

9, a severe degree of leukemia cutis developed during and after the taking of urethane, even though their leukocyte counts were lower than before the institution of therapy (fig. 1). Patient 5 received a combination of urethane and roentgen therapy. Two courses of roentgen therapy (330 r and 440 r) were given with an interval of one month. Urethane was administered immediately after the second course of roentgen therapy, which, incidentally, had been applied to the mouth, the site of extensive leukemic infiltration. The leukocyte count eventually rose to 85,000 at the time of the patient's death, even though urethane was being received. Autopsies were performed in cases 1, 2 and 5. Extensive leukemic involvement of the marrow and other organs was found.

Fig. 2.—Clinical course in case 10 (chronic lymphatic leukemia).

Results have been more favorable in the chronic lymphatic group. Of the 8 patients treated, 3 have died.

One of these, patient 13, a Negro, had been ill for five months. He had extensive lymphadenopathy and splenomegaly when first seen. Hypertensive heart disease was also present. Urethane

was administered for thirty days. During this time his leukocyte count fell to a low level of 117,500. His spleen and lymph nodes decreased only slightly in size. He died suddenly on the forty-fourth day. At this time his leukocyte count was 96,000. An autopsy was not performed and the exact cause of his death was not ascertained.

Case 14 was considered to be a more acute form of chronic lymphatic leukemia. This patient was admitted to the hospital with hemiplegia on the right side which had developed suddenly two weeks previously. He had been in apparent good health until that time. The sternal marrow was heavily infiltrated with lymphoblasts and lymphocytes with numerous cytoplasmic vacuoles. He was given urethane for fifty-two days without any improvement. Death occurred fifty-eight days after urethane therapy had been instituted. This is the only case in the series in which neither clinical nor hematologic change was observed.

Fig. 3.—Sternal marrow before urethane therapy in case 19 (chronic myelogenous leukemia).

Patient 10 (fig. 2) initially received 90 r of roentgen therapy to his spleen in May, 1946. His leukocyte count fell from 228,000 to 12,000 with this small amount of therapy. There was only a slight decrease in the size of the lymph nodes and spleen, however, and he continued to become weak and more anemic. Six blood transfusions (500 cc. each) were given during the following nine weeks. His leukocyte count remained between 8,200 and 12,400, with from 73 to 69 per cent lymphocytes. He was given potassium arsenite solution for two days but could not tolerate the drug because of nausea and diarrhea. He was rehospitalized in July 1946, given three blood transfusions for his refractory anemia and started on a course of 3 Gm. of urethane a day. After eighteen days his leukocytes fell to 1,200 and his erythrocytes to 560,000. Administration of urethane was discontinued, multiple blood transfusions were given, and he gradually improved. After six weeks his sternal marrow smears showed a pronounced decrease in lymphocytic infiltration and an increase in erythropoiesis. The differential blood counts began to show a reduction in lymphocytes. Since Jan. 6, 1947 his erythrocyte and leukocyte counts have been essentially normal. It is impossible to diagnose leukemia from

an examination of his blood and bone marrow. Splenomegaly and inguinal and axillary lymphadenopathy have remained relatively unchanged. This patient has returned to work entirely free from symptoms.

In the remaining cases of chronic lymphatic leukemia there has been fairly good response to urethane therapy. Patient 11 stated that she felt better after a course of urethane than after roentgen therapy. Her spleen diminished in size. Patient 12 had also been previously treated with roentgen rays. Urethane alone, given orally and intramuscularly for forty days, failed to produce a remission. He was given 1,092 r along with urethane, and a remission was promptly induced. This patient died suddenly after what appeared to be an acute myocardial infarction three weeks later. Cases 15

Fig. 4.—Sternal marrow after urethane therapy in case 19. Myeloblasts and premyelocytes have given way to more mature cells.

and 18 are early benign cases. These patients have experienced some hematologic and clinical improvement.

In each of the 4 cases of chronic myelogenous leukemia there has been good response to urethane. Splenomegaly was reduced and fatigability, diaphoresis and headache, when present, disappeared usually after a week of treatment. The leukocyte count approached normal and sternal marrow and blood smears revealed a noticeable change toward maturity (figs. 3 and 4). Patient 19 has had chronic myelogenous leukemia for two and one-half years. Three remissions have been induced (fig. 5). This patient prefers urethane therapy to roentgen therapy which he had previously received in 1945. In the remaining 3 cases there have been similar favorable responses. The fall in leukocyte count may be abrupt or gradual. This fall usually continues after administration of urethane is discontinued. Our

results in chronic leukemia are comparable to those of Paterson and her co-workers¹ and others.²⁰

Two patients with Hodgkin's disease have not been benefited by urethane. In case 19 leukopenia developed after six days of therapy. This patient was transferred to another hospital for more roentgen therapy. Patient

Fig. 5.—Clinical course in case 19.

18, whose disease is refractory to roentgen rays after intensive therapy, failed to show any improvement with thirty days of treatment. She was subsequently given a course of nitrogen mustard therapy and went into a relatively satisfactory remission. Case 21, giant follicle lymphoma, was not improved by twenty-one days of therapy, although a decrease in lymphocytes was noticed. This patient has recently received nitrogen mustard with a rather satisfactory result. In case 20, leukosarcoma with extensive lymphadenopathy, there was good response at first to intramuscular administration of urethane, 2 Gm. three times a day for fifteen days. Lymphadenopathy almost vanished and the symptoms disappeared. Three weeks later weakness and nausea returned. The patient was given urethane orally, 3 Gm. a day for fourteen days, and again felt much improved.

EFFECT ON MALIGNANT NEOPLASMS

Eight cases of malignant neoplasm were treated with urethane. These included: 4 cases of carcinoma of the stomach with metastasis and 1 case each of melanoma, carcinoma of the rectum, retroperitoneal myxo-

Fig. 6.—Leukocyte-depressing effect of urethane in a nonleukemic patient (with carcinoma of the stomach without clinical change).

sarcoma and lymphoepithelioma of the cervical lymph nodes. There was a twofold reason for using urethane in these neoplastic diseases: (1) to determine whether the disease process could be retarded and (2) to observe

20. Kartagener, M.: Urethan bei Leukämie, Schweiz. med. Wchnschr. 76: 821-822 (Sept. 7) 1946. Maringer, S.: Urethan-Behandlung der Leukämie, *ibid.* 77: 114-115, (Jan. 18) 1947.

the effect of the drug on nonleukemic leukocytes. It is impossible to reach any final conclusion regarding the inhibiting effect of urethane on the course of neoplastic diseases because the number of cases studied is small. All but 2 of the patients were in the terminal stage of the disease and were not ideal subjects for any type of cancer therapy. In the case of lymphoepithelioma the disease had been well controlled with roentgen therapy until recently. The patient enthusiastically stated that she felt much better after the first week of urethane therapy, but this may have been an effect of urethane sedation. It is our impression that in no instance was the course of the malignant disease altered. Others²¹ have reported favorable results. Leukopenia developed in 2 cases of carcinoma of the stomach. The leukocytes fell to 1,200 and 2,100. The leukopenia was produced three times in one of these cases (fig. 6). Larger doses of urethane caused a more depressing effect. The leukocyte counts rapidly returned to normal levels after discontinuance of the drug.

EFFECTS ON BLOOD AND BONE MARROW

We have studied the effects of urethane on the morphology of the blood and sternal marrow. Sternal marrow aspirations were performed on 6 patients. Little change in morphology of blood or marrow was noticed in acute leukemia. A diminution in the number of primitive cells and a slight tendency toward maturation were occasionally seen. This change appeared to be only temporary. In favorably responding chronic lymphatic leukemia, the absolute number of lymphocytes decreased and smudge cells were less frequently seen. In chronic myelogenous leukemia the blood and marrow showed a great decrease in immature cells. When these patients were in remission with leukocyte levels below 10,000 the blood smears appeared rather normal. Lymphocytes were, however, rarely seen in the smears. Erythropoiesis and thrombopoiesis were not inhibited by urethane in our cases. In 1 of the patients with metastatic carcinoma of the stomach (fig. 6), in whom leukopenia repeatedly developed when urethane was administered, a marrow change developed at these times similar to that seen in the depressed phase of agranulocytosis. The marrow contained a majority of normoblasts. Myelocytes and promyelocytes were infrequently seen and often contained cytoplasmic vacuoles. Similar vacuoles were seen in marrow myelocytes of chronic myelogenous leukemia after urethane therapy (figs. 3 and 4). In 6 nonleukemic patients lymphocytopenia developed while they were taking urethane. In 3 cases this occurred without a significant decrease in the total leukocyte count.

COMMENT

The place for urethane in the treatment of leukemia cannot be designated precisely at this time. The drug appears to be of little or no benefit in producing remissions or prolonging life in acute leukemia. Its action in chronic lymphatic leukemia is variable but, when effective, produces results comparable to roentgen therapy. It is most consistently successful in controlling the clinical and hematologic abnormalities in chronic myelogenous leukemia. The drug has the following advantages: ease of administration and regulation of dosage, a minimum of toxic side actions, a desirable sedative effect and low cost. Jaffe's warning should be kept in mind when prolonged use is contemplated.

He found an increased incidence of pulmonary adenomas and malignant hepatomas in rats receiving a prolonged administration of urethane and suggested that this might occur in human beings.^{16b} Apparently urethane, like roentgen rays, may at times be carcinogenic.

Urethane may be considered as an additional therapeutic agent available in the treatment of chronic leukemia. We are unable to conclude that it offers any advantage over roentgen therapy other than its ease of administration. We believe that its action is less precise. The drug is more easily administered than are the nitrogen mustards and radioactive phosphorus and, since it is perhaps equally effective in chronic leukemia, its use is to be preferred. Its effects are at times strikingly similar to those of potassium arsenite solution. It is possible that a program of combined therapy consisting of roentgen rays, urethane and nitrogen mustard may be found to be more effective than any one of these therapeutic agents. The nature of the carbamate radical is such that innumerable compounds can be synthesized with it as a component. It is possible that newer compounds which are more therapeutically effective will be found. The mode of action of the carbamates is obscure. Several theories have been suggested but these are based on insufficient experimental evidence. There are indications that the urethanes are nuclear poisons,²² but whether this is due to interference with purine metabolism,⁶ cellular dehydrogenases²³ or other enzyme systems has not been established.

SUMMARY

Urethane (ethyl carbamate) is a potent leukocyte depressant in both normal and leukemic hemopoietic tissues. Satisfactory remissions have been produced in 4 cases of chronic myelogenous leukemia by the oral administration of the drug in doses of 1 Gm. three times a day. Nine patients with chronic lymphatic leukemia have shown a variable response to the drug. Good remissions have occurred in 2 of the patients, some improvement was noticed by 4, and the remaining 3 have died. Severe leukopenia was produced in most of the 9 cases of acute and subacute leukemia without any substantial influence on the course of the disease. No clinical improvement was noticed in 8 cases of malignant neoplastic disease treated with urethane.

ABSTRACT OF DISCUSSION

DR. CLAUDE E. FORKNER, New York: Leukemia is a disease of unknown cause and without satisfactory treatment. I think we still can say that in spite of this excellent work with ethyl carbamate, or urethane, this new agent does not, in our present knowledge, add much to our ability to treat leukemia effectively. The studies are important, however, because through them new information may be gained which may provide an approach to the understanding of the mechanisms by which the disease may be influenced. The most fundamental facts about the production or destruction of white blood cells are not known. There has been no systematic study of the blood-forming organs with respect to what causes regeneration and destruction of the white blood cells or even of the red blood cells. Our information on these points is only fragmentary. Urethane offers a new tool to add to our armamentarium for the treatment of leukemia. Among the tools which we now have are irradiation by means of roentgen rays, radium, radio-phosphorus; the use of arsenic, particularly in the form of potassium arsenite, the use of benzene, which has more or less

been discarded, and the use of nitrogen mustard. All these agents must be used with care. None of them ever cures the disease; all may be dangerous. It is of some importance that the agents which we use to treat leukemia are of themselves carcinogenic. This may be a reason why no known agent is thoroughly satisfactory, because in the treatment of leukemia, we may be simultaneously rendering that person more susceptible to the disorder. The results with urethane correspond somewhat to those achieved with other methods. All these methods are more effective in the treatment of chronic myelogenous leukemia. They are a little less effective in the treatment of chronic lymphogenous leukemia. None of them is effective in the treatment of acute leukemia. Spontaneous remissions do occur, particularly in acute leukemia. Some of the instances in which ethyl carbamate has seemed to be of value may be purely spontaneous remissions. It is too early to judge whether this agent is going to be as effective as other agents, but it seems from our own small experience and from the literature that perhaps it is not as effective as the agents which we now use in the treatment of the disease. The important point to be stressed here is that this new agent may offer an opportunity to learn something about the mechanism of what is going on in the leukemic patient and learn something about the mechanism of blood formation and blood destruction.

DR. LEON O. JACOBSON, Chicago: Working with the nitrogen mustards and more recently with urethane has given some opportunity to compare the therapeutic value of a number of agents. We have used urethane in the following ways: We have attempted to induce repeated remissions in myelogenous and lymphatic leukemia of the chronic variety, and in lymphomas, and particularly Hodgkin's disease. After remissions have been induced in the lymphomas and particularly Hodgkin's disease by roentgen ray or nitrogen mustard, an attempt has been made to maintain a long remission by giving urethane. We have also used urethane in metastatic carcinoma of the breast. In our limited experience, we have been able to produce and maintain brief remissions in chronic lymphatic and chronic lymphadenous leukemia, but feel in general that the remissions produced were shorter and less satisfactory from the hematologic and symptomatic point of view than those produced with roentgen therapy, with phosphorus 32, in selective cases, and with nitrogen mustards. In those cases of Hodgkin's disease in which a clinical remission had been produced with roentgen rays or with nitrogen mustards and then urethane was given, we were unable to prolong the remission. These patients had been treated repeatedly for various periods of time with roentgen rays or nitrogen mustard; thus we knew approximately how long remissions could be expected to last in individual cases. Urethane did not prolong the remission or even make it more complete. Cancer of the breast with generalized metastasis was not affected in our limited experience. Urethane seems to control myelogenous leukemia more effectively than lymphatic leukemia. As you know, radiation and nitrogen mustard produce more profound effects on lymphatic tissue than on myelogenous tissue. Further work may indicate that urethane will be useful as an adjunct to roentgen rays in various neoplasms. The results obtained thus far by various workers using urethane, nitrogen mustards and other chemotherapeutic substances have given a definite stimulation to work on the modification of these compounds and the search for other more effective chemotherapeutic agents. Even with these agents the treatment of these diseases is unsatisfactory at present. I would like to ask Dr. Hirschboeck to tell a little more of the toxicity which he encountered in his cases.

DR. EDWIN E. OSGOOD, Portland, Ore.: As a part of a long term study of the fundamental nature of growth at the University of Oregon Medical School along the lines that Dr. Forkner mentioned, Dr. Chu I-Tung and I have included a study in marrow cultures of the action of urethane. I should like to ask Dr. Hirschboeck whether he has noted changes in the granulocyte series similar to those that I will show. In the marrow culture, we have a method for controlled quantitative study of living human cells. We were able to compare the action of 200 kilovolt roentgen rays, radioactive phosphorus, neutron rays, million volt roentgen rays, colchicine, urethane and nitrogen mustards. I want to show the changes that

occurred in the cells in the urethane series which were not observed in the controls or with any of these other agents. The first thing noticed was an increase in the number of mitoses occurring as early as three hours and reaching a maximum at twenty-four hours. This doubtless accounts for the increase in cell count observed early by Dr. Hirschboeck. The most common change noted and seen chiefly in granulocytes and progranulocytes was that the basichromatin is aggregated in clumps with persistence of the nuclear membrane. A less frequently observed effect was complete loss of nuclear membrane with fragmentation and karyorrhexis rather than a colchicine-like effect. The number of fragments were too few for them to be altered chromosomes, and they were more rounded than with colchicine. Urethane does not affect all the cells. A common development after the third day was the appearance of double nuclei in cells of the granulocyte series, first in the progranulocyte and later in more mature cells. Such double nucleated cells are extremely rare in the granulocyte series, though common in cells that divide by amitotic division. Clinically, we have observed similar results to those reported by Dr. Hirschboeck but agree with Drs. Forkner and Jacobson. We feel that results from urethane are inferior to those with regularly spaced total body irradiation or injections of radioactive phosphorus. In the 1 case of malignant tumor reported in the correspondence section of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION by Goodman and Lewis we observed the most striking regression in a metastatic malignant tumor that I have ever seen with any method of therapy.

DR. WILLIAM DAMESHEK, Boston: I had the occasion yesterday in the Section on Experimental Medicine and Therapeutics to discuss two other chemotherapeutic methods, namely, the use of nitrogen mustard in Hodgkin's disease and the use of "stilbamidine" in multiple myeloma. It is possible that we may now be at the threshold of a chemotherapeutic era for the treatment of the proliferative disorders of the white blood cells. Urethane has a definite effect, particularly in chronic myelogenous leukemia. In relatively early cases an excellent remission may be obtained, and this can be continued for at least a few months by the use of the drug in relatively small dosage. In the severe cases with a large spleen, some effect on the white cell count may be obtained, but there may be little reduction in the size of the spleen. In these and other cases of advanced chronic myelogenous leukemia, roentgen therapy appears to be far more effective than urethane. What is more, when the drug is discontinued or its dosage diminished, there is usually a quick relapse, with a rapid rise in the leukocyte count to high levels. One great advantage of the various chemotherapeutic methods which are now in the process of development is that they allow complete control of therapy by the internist or hematologist rather than the divided control which is essential in roentgen therapy. The radiologist naturally likes to control his own particular apparatus, and we like to control our patient. Often some degree of conflict occurs, which will be avoided as chemotherapeutic methods continue in their development. It is the hope for the future that continued study in this field will lead to methods for the control of the abnormal metabolic activities of the proliferating white cells.

DR. JOHN S. HIRSCHBOECK, Milwaukee: In answer to Dr. Jacobson's question regarding toxicity, I may state that we believe that urethane may cause two types of nausea and vomiting. One is due to a local gastric irritation occurring in a few patients after the ingestion of as little as one or two doses of the drug. The other appears to be central in origin and occurs late in the course of therapy, even when enteric-coated capsules are used, and may persist for several days after the drug is discontinued. One of the patients with chronic lymphatic leukemia showed evidence of nephritis at autopsy. This may have been a toxic effect of urethane. We have not noticed morphologic change in the blood or marrow other than the cytoplasmic vacuoles which were described. Urethane therapy is, of course, still experimental. We feel that the drug is of definite value in chronic myelogenous leukemia and should be used to supplement or substitute for roentgen therapy. It is particularly suitable for patients who do not live near a roentgen therapy center.

Special Article**CANCER OF THE NERVOUS SYSTEM**

Brain, Spinal Cord and Peripheral Nerves

HOWARD C. NAFFZIGER, M.D.

and

EDWIN B. BOLDREY, M.D.
San Francisco

This article is the fifth of a series to be published by the American Medical Association in cooperation with the American Cancer Society. The series is designed to aid in the early diagnosis of cancer and thereby to gain more effective results in treatment. When complete, the series will be published in book form by the W. B. Saunders Company under the sponsorship of the American Medical Association and the American Cancer Society.

Since the end of World War I impressive advances have been made in our knowledge of the biologic characteristics, modes of early diagnosis, and treatment of tumors affecting the nervous system. It is now recognized that these tumors, once considered rare, constitute 2 per cent of all cancers. The early diagnosis of this group has been materially aided by improvement in the knowledge of the physiology of the nervous system as well as by technical developments, notably pneumoencephalography, cerebral angiography, myelography and to some extent electroencephalography.

Through improvement of surgical and anesthetic technique the operative mortality in brain tumors is at a level comparable with that of major surgical operations elsewhere in the body. The percentage of surgically curable tumors is gradually being enlarged. Improvement in roentgen therapy is prolonging the useful life of increasing numbers of patients with nonremovable growths.

The side effects of brain tumors have also become controlled more satisfactorily during this period of time. Convulsions, which are one of the most frequent complications of brain tumors, are reduced in frequency or are eliminated entirely by a variety of anticonvulsant drugs which have been developed in recent years. Improved knowledge of endocrine function has minimized the distressing effects of tumors of the intracranial endocrine glands and centers. Developments in these two particular lines have reduced the incidence of psychic disturbance resulting from the projection of endocrine or convulsive disease into the patient's life.

INTRACRANIAL TUMORS

The term intracranial tumor has come to include all the intrinsic tumors of the brain, the pituitary and the pineal glands, the cranial nerves and the meninges as well as those tumors of the skull which come to invade the intracranial space. Daughter growths from cancer elsewhere in the body also are included.

Successful treatment of an intracranial tumor depends on its type, its accessibility, the extent of its involvement of important areas (speech, motor, medulla) and the stage at which it is diagnosed. More than 50 per cent of all brain tumors fall in the favorable group if there is reasonably early diagnosis and if the treatment is properly executed.

EARLY DIAGNOSIS OF TUMOR OF THE BRAIN

Tumor must be thought of whenever the symptoms and signs are those of a progressive single lesion. The onset usually is insidious but occasionally is precipitous as in glioblastoma multiforme. Certain generalities may give some support to the early suspicion that a neoplasm may be present. Thus, most tumors in adults occur above the tentorium; a notable exception is the cerebello-pontine angle tumor, or perineurial fibroblastoma of the eighth (auditory and vestibular) nerve. As with all other growths, brain tumors in adults have their highest incidence in the cancer age of the fourth, fifth and sixth decades. Most brain tumors of childhood are of the cerebellum, with the supratentorial exception of the epithelial cysts near the pituitary (Rathke's pouch cysts, craniopharyngioma). These general trends, however, are valuable only as positive support for an impression of tumor and not in a negative way to rule out other etiologic factors.

Brain tumor may manifest itself in three ways: first, by local irritation of some structure of the central nervous system which produces a convulsion or some other evidence of uncontrolled nervous discharge; second, by focal paralysis of some part of the brain, or of one or more cranial nerves, which diminishes or eliminates thereby the function of the part affected; third, by an increase of intracranial pressure because of the size and space-occupying nature of the tumor, or because its presence blocks the pathways of cerebrospinal fluid between the ventricles and the site of absorption. Signs of local irritation or of local pressure usually are earlier signs than are those of general pressure, though some tumors by their location may block the fluid pathways at a relatively early date.

Convulsions which start in adult life constitute one of the more frequent early signs of tumor affecting the cerebrum. The neurologic axiom has developed that the initial appearance of convulsions in an adult must be regarded as evidence of a brain tumor until proved otherwise. Both intrinsic and extrinsic tumors may irritate the cortex, thus producing such a discharge. In the so-called silent areas of the brain the tumor may reach considerable size before manifesting itself in this way, but in the more responsive regions tiny growths may thus give evidence of their presence. If the motor cortex is affected a jacksonian type of fit may be anticipated. If the somatosensory cortex is involved a sensory pattern of numbness, tingling, electricity or pins and needles in the affected part may predominate in the early phases. If the inner aspect of the tip of the temporal lobe is involved olfactory or gustatory hallucinations may be observed. Tumors around the sella turcica may produce these phenomena. If the upper posterior part of the temporal lobe is affected there may be auditory hallucinations. Visual hallucinations come from irritation in the occipital region. The appearance in an adult of hallucinatory phenomena, recurrent and of a fairly regular pattern, should make one think of an early brain tumor. If the lesion involves the dominant hemisphere, transitory difficulty in speech may be an early manifestation of brain tumor and should be regarded as an irritative phenomenon, probably originating in the depths of the hemisphere.

Focal paralysis of function may appear after an initial period of irritation or may occur as an initial symptom. Weakness of an extremity progressing both as to degree and as to extent of involvement may occur if a tumor is developing in the motor cortex. The progress of a

* From the Department of Neurosurgery, University of California Medical School.

weakness from one extremity to its fellow on the same side, such as from the right leg to the right arm, should be particularly suggestive. Reflexes are usually increased and pathologic reflexes may be present. Involvement of the postcentral cortex may result in progressive loss on the opposite side of stereognosis, recognition of figure writing on the skin and identification of texture, form and weight (deep sensation). Defects in the visual fields may result from a lesion involving the optic tract anywhere between the occipital lobe and the optic foramen; a lesion posterior to the optic chiasm would produce a defect homonymous in character; one anterior to the chiasm would probably affect one eye alone. Focal lesions below the tentorium may paralyze single or successive groups of cranial nerves. Involvement of the cerebellar tracts or nuclei will produce impaired coordination.

Alteration in temperament may be an early manifestation of a brain tumor, particularly of the intrinsic type (glioma). This seldom persists for any long period of time as an isolated complaint. Most temperamental changes are associated with either frontal or temporal lobar lesions. Some personality change may appear in conjunction with generalized increase in intracranial pressure. Overt psychopathic states are not common.

The usual symptoms of increased intracranial pressure are of generalized headache, drowsiness, nausea, vomiting and slowness of the pulse. Ocular papilledema (choked disks) almost always occurs. In the child a cracked-pot note may be elicited on tapping the skull. If the pressure is the result of a tumor in the region of the third ventricle there may be associated metabolic changes such as increase in weight, altered sexual activity and changes in water metabolism. A block at the aqueduct of Sylvius may add interference with conjugate movement of the eyes in an upward direction. A block in the region of the fourth ventricle may produce ataxia, nystagmus and weakness or paralysis of cranial nerves.

Once a growth is suspected special studies may be necessary to positively identify the tumor. Plain roentgen ray films of the skull may show localized erosion, proliferation of bone or unusual vascular markings. Tumors of or near the pituitary may enlarge or deform the sella turcica. Decalcification of the dorsum sellae is characteristic of generalized intracranial pressure. Tumors arising from the eighth nerve sometimes enlarge the internal auditory canal. Deposition of radiopaque material such as calcium may appear in almost any type of neoplasm; occasionally it is seen in certain of the cysts, such as Rathke's pouch cyst; it may also occasionally be seen in the walls of aneurysms. Probably the most valuable lateralizing sign of tumor to be obtained from roentgenograms of the skull is that of shift of a calcified pineal gland away from the side of a tumor. Occasionally in lateral films its displacement in the anterior-posterior direction may be demonstrated. Deposits of calcium in the choroid plexus must not be mistaken for a displaced pineal gland.

Roentgen studies following replacement of the ventricular and subarachnoid fluid with air or oxygen may give further valuable information. If the pressure of the spinal fluid is normal, this procedure can be performed by the lumbar route (pneumoencephalography); if the pressure is elevated, bur openings are made in the skull and the air is introduced directly into the ventricular system (ventriculography). By this method it is often possible to localize the tumor accurately, and at times its possible nature may be suggested. This procedure

should be carried out only when equipment and personnel will permit it to be followed immediately by operative treatment should this be found necessary.

The recent development of carotid arteriography, wherein radiopaque material is injected into the carotid arteries while roentgenograms are taken in rapid series, has opened up still further fields of study. Arteriograms are particularly adapted to early demonstration of tumor and may occasionally be of some value in the identification of the type of tumor.

GLIOMAS

Gliomas, which are the intrinsic tumors of the brain, constitute approximately 50 per cent of all intracranial tumors. These growths are composed of neuroectodermal cells, most of which are glial in character, though tumors containing neuronal elements are included. In a general way the cells of tumors of this group are similar to glial cells in various stages of embryonic growth and development, and the nomenclature now generally accepted, based in large part on that developed by Bailey and Cushing in 1926, reflects this apparent relationship between embryonic and neoplastic cells.

All gliomas, being invasive growths which tend to recur locally, must be regarded as malignant tumors. Recurrence can be eliminated or significantly delayed only through early recognition and treatment before essential areas have become invaded by the neoplastic process. When the tumor arises in such a region, the problem, of course, is resolved as it commences.

Astrocytoma.—The astrocytomas, which constitute somewhat more than one fourth of the gliomas of the brain, are the commonest of the gliomas. About 65 per cent of the astrocytomas are cerebral, approximately 18 per cent arise in the cerebellum and approximately 10 per cent occur in the brain stem and the region of the third ventricle. The sex incidence of astrocytoma is about evenly divided. The age incidence in the cerebrum and in the cerebellar hemispheres is greatest in the fourth and fifth decades. In the cerebellar vermis the incidence is highest in the first and second decades. The period of symptomatologic manifestations and the survival depend not only on the type of tumor growth but on the location.

There are three subtypes of astrocytoma. Fibrous (piloid) astrocytomas are composed of cells rich in fibers, with small nuclei scattered throughout the neoplastic mass. These tumors are found in the cerebrum and in the cerebellum. The cerebral groups are firm, pale and gelatinous and may contain small cysts or occasionally a large one. By involvement of whole gyri and by their firmness they may give a false appearance of being well demarcated. In the cerebellum large cysts containing yellow fluid which clots on removal are frequently encountered. In these the active tumor usually is found as a nodule in some portion of the cyst wall (mural nodule), removal of which is often completely curative. Of all the gliomas this tumor carries the best prognosis. Survivals of over three years following extirpation of cerebral astrocytomas are not at all uncommon.

Protoplasmic astrocytoma (diffuse) is more commonly seen in the cerebrum. The cells infiltrate the white and gray matter, stimulating satellitosis about nerve cells and stifling their activity by force of numbers of invading cells. These diffuse tumors may cause irritation and produce convulsions, but they progress so insidiously that a mass may not be evident until late in the disease. At operation a generalized widening of

gyri and narrowing of sulci may be seen, but the limits of the tumor may be poorly defined. The tumor type can be identified by biopsy. Fortunately this tumor is fairly responsive to roentgen therapy.

Gemistocytic astrocytoma, composed predominantly of Nissl's plump cells, is the third variant of the astrocytoma group. This tumor also is more commonly found in the cerebrum. It is the most rapidly growing of the astrocytomas, has the shortest history and is the most unfavorable of the group. Its preoperative history is usually but slightly longer than that for glioblastoma multiforme; postoperative survival, however, is significantly longer. Grossly these tumors are usually reddish and gelatinous or meaty in appearance. Cysts are uncommon and when present are usually small, probably representing areas of degeneration. The invasive proclivity of the tumor is midway between that of the protoplasmic astrocytoma and the suggestive encapsulation of the fibrous astrocytoma. The tumor is not as solid as the noncystic fibrous astrocytoma. Areas of degeneration may cause it to be mistaken for glioblastoma multiforme, grossly as well as microscopically. Postoperative survival of from one to two years is not uncommon. As with other tumors predominantly cerebral in location, the problem of convulsions may be a major one.

Glioblastoma Multiforme.—The second most common of the gliomas, constituting about one fourth of this group, is glioblastoma multiforme (spongioblastoma multiforme). It occurs far more frequently in the cerebrum than elsewhere, although it has been described in the brain stem and the cerebellum as well as in the spinal cord. It affects males more frequently than females in a proportion of about three to two. The age incidence is greatest in the fourth, fifth and sixth decades; however, instances have been described in the very young and the very old. Glioblastoma multiforme may come on with precipitous suddenness, striking a man in the prime of life completely without warning. The sudden onset may be so striking as to cause confusion and an erroneous diagnosis of a vascular accident. The progress of the disease, however, will usually give early evidence that the problem is no ordinary hemorrhage or thrombosis. The average total duration of symptoms is between six months and a year. However, patients who have been treated early and radically have survived as long as five years after the first diagnosis. About one third may be expected to live longer than one year if removal is accomplished early and is combined with roentgen therapy.

Glioblastoma multiforme appears to originate most commonly in the white matter of the brain and tends to travel by the tracts of the brain, crossing to the contralateral side by the corpus callosum and going into the brain stem by way of the major pathways to and from the cerebrum. It invades the gray matter indiscriminately, however. The tumor is usually soft and succulent, containing large areas of degeneration. Cysts of varying size, which contain reddish yellow fluid, may be encountered. These may develop in a relatively short period of time. Large vascular channels, some of whose walls apparently take part in the neoplastic process, course through these growths. Occasionally firm tissue of mesoblastic origin may be found at the surface. The tumor may have the appearance of being encapsulated, but deeper it will be found in continuity with the underlying white matter. Variations in color and occasional small collections of frank clots

suggest that extravasations of blood may occur in these tumors with some degree of frequency.

Microscopic study reveals cells of varying size and type. There is no recognized cell which is named the glioblast. The cells of the tumor include almost every variant of the glial series. The blood vessels show striking proliferation of the adventitia and intima, suggesting that the vascular system plays a role in this neoplastic process greater than that usually found in other tumors of the glioma series. Frank obliteration of vascular channels with recanalization and vascular budding also is observed.

If glioblastoma multiforme is encountered early and in an area from which it can be extensively removed, many months of useful and pleasurable life may be anticipated for the properly handled patient. Those tumors originating in more vital centers are, of course, difficult to handle and carry a proportionately increasing gravity of outlook with the importance of the center affected.

Medulloblastoma.—Medulloblastoma is the commonest glioma of childhood. It constitutes about 14 per cent of all the gliomas. This tumor practically always arises in the cerebellum and involves the fourth ventricle at an early stage. Males are affected more than females in the proportion of two to one. The average age is in the latter half of the first decade, but the tumor is fairly commonly seen throughout the first decade and into the first half of the second. Because this tumor occurs so frequently during a period when a certain degree of clumsiness is anticipated, the early signs of incoordination are not apparent or are ignored until signs of generalized pressure appear. A story of recurrent bouts of headache, nausea and vomiting culminating in recognition of impaired coordination or reduced vision due to extensive papilledema is all too common. Children with recurrent attacks of nausea, vomiting and headaches should be observed for changes in coordination, for changes in the note on tapping the skull and for evidences of papilledema.

Medulloblastoma is usually a soft, friable, cyanotic mass with little supporting connective tissue, and when presenting into the ventricle is covered at the surface by a filmy membrane no thicker than the arachnoid. Its friability permits cells to float out into the subarachnoid space, setting up daughter growths in the spaces of the cranium and of the spinal canal. The appearance of encapsulation is a false one, for the tumor is quite invasive. Because of its location and proximity to the brain stem it can never be regarded as having been completely removed surgically. Fortunately, it is responsive to roentgen therapy, which should always be used in addition to surgical procedures. Survivals of from one to five years are not at all uncommon in medulloblastoma when roentgen therapy is judiciously used in conjunction with treatment by surgical means.

Cerebellar Sarcoma.—A tumor in the cerebellum of older persons, having cells morphologically similar to those seen in medulloblastoma of childhood but associated with more extensive reticulin formation, the cerebellar sarcoma has been the subject of considerable discussion among neuropathologists. Some regard this tumor as essentially the same as the medulloblastoma of childhood. Others have regarded it as a cerebellar sarcoma differing from cerebellar medulloblastoma in all characteristics except its usual anatomic location.

Ependymoma.—Ependymoma constitutes about 10 per cent of the gliomas. This tumor is widely distributed

through the cerebrum, brain stem and the spinal canal, being the most frequently observed glioma of the spinal canal. It is reported more frequently in females than in males in a proportion of about two to one. The age incidence of the tumor in the brain reaches a peak in the third and fourth decades. In the cerebellum and brain stem it has a tendency to rise from the floor of the fourth ventricle and has been described in this location in the first few years of life. It is a fairly common glioma of childhood in the cerebrum.

Cerebral ependymomas frequently have connection with the ventricular system; a large percentage of the gliomas going into the lateral ventricles are ependymomatous in character. They are usually moderately firm, but cysts may be encountered. They grow slowly, the symptoms persisting for up to three or four years before their nature is manifest. Ependymomas of the posterior fossa usually block the fourth ventricle early in their course, giving rise to generalized increased pressure as an early sign. The postoperative survival in ependymomas depends on the location. Survivals up to five years are not uncommon. The tumor is fairly resistant to the therapeutic effect of the roentgen ray.

Polar Spongioblastoma.—Polar spongioblastoma (spongioblastoma polare) is most commonly seen in the region of the pons, the optic chiasm and the corpus callosum. The course of the disease is usually slow and insidious. The symptomatology is that of progressive involvement of the area of origin; that is, progressive loss of vision in tumors of the chiasm, progressive involvement of successive cranial nerves at their nuclei of origin if the pons is affected. The tumor cells insinuate themselves into the tracts or nuclei, finally stifling function by their overgrowth. Generalized pressure occurs late with tumors in the chiasm and is almost unheard of with those in the pons. These tumors in the corpus callosum are characterized by the mental disturbance so commonly seen in primary lesions of the corpus callosum. Disorientation, fabrication and delusion are frequent manifestations of such lesions.

Polar spongioblastoma constitutes about 5 per cent of the gliomas. It is slightly more common in the male than in the female. The age incidence of the tumor in the pons and in the chiasm is through the latter part of the first and into the second decade. Polar spongioblastoma of the cerebrum elsewhere, and particularly of the corpus callosum, is a tumor of adult life with a peak in the fourth and fifth decades.

This tumor is usually not amenable to surgical intervention because of the regions which it commonly involves. It is moderately susceptible to roentgen therapy, particularly in the basilar region. Patients have been carried along successfully for several years by the judicious therapeutic use of roentgen rays.

Oligodendroglioma.—About 5 per cent of the gliomas are oligodendrogliomas. The tumor may be indolent, and symptoms, in which convulsions predominate, may continue over several years before the identity of this slowly developing growth becomes manifest. Nearly all oligodendrogliomas are found in the cerebrum. They appear to commence in the white matter and slowly invade the adjacent gray. The age incidence is greatest in the fourth and fifth decades. The tumor appears to affect male and female about equally. Because of its slowness of growth, calcification is commonly found in the tumor. The tissue is usually moderately firm, but its area of extent is poorly outlined. Cysts are rare.

Periods of survival up to several years following surgical intervention are frequently seen. This is

regarded as being related to the slowness of growth inherent in this tumor rather than to the successful extirpation of the entire lesion. Sudden changes in the rate of growth are particularly common in this tumor, and changes in cell types may be found at subsequent examinations. The tumor is but moderately responsive to the effect of the roentgen ray.

MENINGIOMAS

Tumors of the meninges constitute approximately 16 per cent of brain tumors. They are most frequently encountered above the tentorium and therefore affect the cerebrum more frequently than the cerebellum and brain stem. They are found in females more frequently than in males in the proportion of about three to two. The age incidence is highest in the fifth decade, one third of Cushing's series, for example, being first observed in this period. Instances have been reported, however, from the first to the ninth decades of life. Interestingly, the average age of symptomatic onset is apparently about eight years younger than that for initial study, and patients are reported to have had convulsions for thirty years before treatment of a causative meningioma. Most of these tumors, however, will not permit such a lag between onset and treatment. The average rate of progress is fairly rapid, being a matter of only months in some cases.

Because of the location of the majority of meningiomas in relation to the cerebrum, convulsions are a major initial symptom. Sometimes the tumor will invade the skull, producing a bump on its outer surface which indicates its presence; sometimes progressive paralysis will occur without preceding irritative phenomena. Meningiomas at the base may block the cerebrospinal fluid pathways and produce generalized pressure as an initial symptom.

Meningiomas usually arise from the arachnoid, though there is generally an attachment to the dura and some primary tumors of the dura have been described. The tumor may grow primarily into the cranial cavity and may not produce demonstrable change in the adjacent bone. It may produce a thickening of the inner table of the adjacent skull; cells may invade the haversian canals to produce thickening of the inner and outer tables; invasion of the skull may reach the point at which there will be an erosion with considerable projection of tumor into the subgaleal space on the outer surface of the skull. The growth of most meningiomas is associated with a striking increase in vascular supply, and at times this will be manifest in plain roentgen ray films of the skull.

It is generally considered that there may be some relationship between these tumors and the arachnoidal granulations. The usual location of these tumors, which is most frequently close to one of the major dural sinuses, has some bearing on this possibility. Tumors of the olfactory groove and the tuberculum sellae are not uncommon.

Usually these tumors push the brain ahead of them and do not invade it. There may be pressure erosion of the pia, however, and extremely nodular tumors may come to incorporate isolated bits of brain in the crevices between the projecting nodules, producing, from a practical standpoint, invasion of the cerebrum itself.

The prognosis in meningioma is in general better than that for tumors of the glioma group. The vascularity plus the tendency to invade the skull, which are so frequently associated with meningiomas, make them a complicated one.

operation. Tumors attached to the sagittal sinus or the torcular, or plaque tumors overlying these essential structures, may recur, but the tumor type seldom changes and reoperation is to be regarded as justifiable when necessary. Meningiomas have been regarded as resistant to roentgen therapy, though favorable results are beginning to appear in the recent literature. The major complicating factor in meningioma is the convulsive state which may result from irreversible changes in the adjacent brain. These are controlled by the usual anticonvulsive regimen.

CEREBELLO-PONTINE ANGLE TUMOR

Cerebello-pontine angle tumor (eighth nerve tumor; neurinoma of the eighth nerve; perineurial fibroblastoma of the eighth nerve; acoustic neuroma) is said to constitute about 10 per cent of intracranial neoplasms. This tumor usually arises from the perineurium of the acoustic nerve just at or in the porus acousticus. It affects females more than males in the proportion of three to two and is most commonly found in the fourth and fifth decades of life. These growths may be bilateral, and their occasional association with von Recklinghausen's disease (neurofibromatosis) has been reported. The usual early symptoms are progressive loss of hearing in one ear, sometimes with tinnitus and occasionally but not commonly with some dizziness. Attacks of dizziness, such as those seen in Ménière's syndrome, are rare. Because of the proximity of the facial nerve in the porus acousticus, some involvement by pressure, manifesting itself as weakness of movement of the face, may be seen, usually as a late manifestation of the disease. As the tumor enlarges it may press on the ninth, tenth and eleventh nerves as well as the fifth and the third anteriorly. It may grow in front of the pons and may so distort the brain stem as to produce some signs of involvement of the opposite side, even when bilateral tumors are not present. It may press on the tract and the nuclei of the cerebellum to produce signs of cerebellar disease, again as a late manifestation of the tumor.

The tumor is usually encapsulated. Inside the capsule there may be areas of cystic degeneration, occasionally of gratifying size. Much of the tumor ordinarily is yellow and soft, but the presence of firm, fibrous trabeculae with ample blood vessels is common and makes removal difficult. It usually has a network of blood vessels over its capsule, and there may be intimate adhesions between it and the brain stem, the medulla and pons. The seventh nerve is commonly bound up in the wall of the tumor so that complete extirpation, at least in the late stages, is usually associated with paralysis of the seventh nerve.

When located early, these tumors can be completely removed and the patient cured with no incapacity other than the loss of hearing due to sacrifice of the affected eighth nerve. Unfortunately, they are seldom discovered before there has been involvement of other cranial nerves and of the brain stem to the extent that complete removal is difficult or impossible. In such circumstances the surgeon generally has resort to subtotal intracapsular removal. Since the tumor does not ordinarily change its cytologic characteristics, reoperation when the tumor recurs is justifiable and patients may be carried along for many years of happy and useful life. The tumor is but moderately responsive to roentgen therapy.

Nowhere in brain tumor surgery is the necessity of early diagnosis more striking than in the case of this

tumor. Most patients with it have had a history of progressive loss of hearing on one side for many years. If one waits for evidence of involvement of the cerebellum or of other cranial nerves, the tumor is already too large to be approached without great hazard and the chance of getting a complete extirpation is materially reduced. Erosion of the porus acousticus, when definite, is a good positive sign; but its absence is a poor negative one, for the site of origin of many tumors is such that involvement of the bone occurs late or not at all. Nerve type loss of hearing that is unilateral and progressive should be regarded as potentially due to a tumor of the eighth nerve until proved otherwise.

Tumors similar in pathologic characteristics to that arising from the eighth nerve have been found arising from other cranial nerves, notably the tenth. Under such circumstances the symptom complex is that of progressive involvement of the nerve affected, those adjacent and, of course, the brain stem and cerebellum.

PITUITARY TUMORS

The incidence of adenomas of the pituitary gland is reported in widely varying figures, presumably related to the particular interests of the investigator. Probably the incidence is about 5 per cent of all intracranial tumors. Primary tumors of the pituitary are most commonly adenomas of the anterior lobe. Of these, chromophobe adenomas are two and one-half to three and one-half times more common than the next most frequent type, the eosinophilic adenoma.

Chromophobe adenomas give evidence of their presence by progressive reduction of sexual activity and other endocrine function. Pressure on the optic chiasm producing impairment of vision, usually having some or all of the aspects of bitemporal hemianopsia, may be the first sign. Some tumors may burst laterally from the sella turcica, compressing the third, fourth, fifth or sixth cranial nerves or irritating the hippocampal gyrus, thus producing uncinate fits. The tumor may grow into the posterior fossa, producing pressure on the brain stem as a late manifestation.

Eosinophilic adenomas are responsible for the well known syndrome of acromegaly quite early in their development. They usually do not reach the size that is common with the chromophobe adenomas but may produce similar changes in the visual field.

Basophilic adenomas are not regarded as reaching such a size as to make them of surgical importance.

Usually the surgical treatment of pituitary adenoma (chromophobe and eosinophilic) is directed toward the preservation of vision, and it is most effective early when the defect is confined to the bitemporal fields. Delay seriously increases the probability of permanent visual impairment. In advanced stages the mere decompression of the nerve by removal of the tumor may alter the physiologic relationship and result in complete blindness. Delay to such a point, however, is indefensible, since the clinical history plus roentgenograms of the skull showing enlargement of the sella turcica are seldom atypical. In the rare instance in which sellar enlargement is not demonstrable, progressive visual loss demands the use of encephalography for study of the parasellar region.

Pituitary adenomas are sometimes cystic. It may be feasible to remove an early growth completely, sometimes preserving a considerable amount of normal pituitary gland. The tumor cells are moderately sensitive to roentgen radiation. The initial swelling which follows roentgen radiation may cause increasing loss of

vision, however, and it is usually considered advisable to decompress the optic nerve surgically first. Another reason for advising surgical decompression first is that other tumors insensitive to roentgen radiation may mimic the effect of pituitary adenoma.

TUMORS OF THE HYPOPHYSIAL DUCT

Tumors arising from cell rests brought into the region of the sella turcica by the forerunner of the anterior lobe may give rise to epithelial tumors in or above the sella turcica (Rathke's pouch cyst; craniopharyngioma; pituitary adamantinoma). Slowly growing and usually cystic, they give evidence of their presence by pressure on the pituitary gland. They produce delayed sexual development or alteration of sexual function if puberty has already been reached. They may press on the structures in the region of the third ventricle, producing metabolic changes, dwarfism and obesity; by pressure on the optic nerve they impair vision. Unlike the pituitary adenomas, these tumors are usually seen in the first, second and third decades of life. Roentgenograms of the skull will commonly show changes in the sella turcica. There may be calcification in the walls of the cyst permitting it to be identified on this basis alone. These cystic tumors are not susceptible to roentgen therapy, but surgical extirpation, while often incomplete because of attachment of the tumor to vital centers, may be expected to give dramatic symptomatic relief, particularly with respect to vision. Early diagnosis and close medical supervision usually permit a favorable outlook for many years. Failure of sexual maturation presents a more difficult problem of therapy; by the time the diagnosis is made irreversible changes often have occurred.

EPIDERMOID AND DERMOID CYSTS (CHOLESTEATOMA; PEARLY TUMOR)

Wherever in embryonic life there has been infolding of the ectoderm, the inclusion of epithelial cells which maintain their more primitive characteristics of epithelium is possible, and the proliferation of these cells produces cystic tumors. If only the ectoderm is involved the resulting cyst is an epidermoid; dermoid cysts contain ectodermal and mesodermal elements. The rare teratoma will contain elements of all three germ layers.

In the cranium epidermoid and dermoid cysts are found in the third ventricle, in the posterior fossa and in the skull itself at points where there is infolding, as at the lateral margin of the orbit. The tumors give evidence of their presence by pressure on adjacent structures. In the third ventricle increased intracranial pressure is a common early sign. The tumors appear in the first three decades of life most commonly, though their slow growth may delay evidence of their presence until as late as the seventh decade. These cysts are encapsulated and when not intimately adherent to adjacent vital structures may be completely removed. If not totally removable, excavation of the content of the cyst may ameliorate symptoms for prolonged periods of time.

VASCULAR TUMORS

Angiomas.—Angiomas may affect the brain at any age and may manifest themselves at any age level, but generally evidence is present in the first three or four decades of life. Angiomas are generally regarded as congenital malformations of blood vessels, which enlarge by expansion of the vessels already present rather than by direct proliferation of cells. Three types of tumors are recognized; namely, telangiectases, and

venous and arteriovenous angiomas. They usually manifest themselves by the production of convulsions, probably due to scarring which results from the enlargement of the vessels and occasional small hemorrhages. Calcium is often laid down in the wall of these vessels, and the tumor then may be identified by plain x-ray films. The arteriovenous angiomas may have an accompanying bruit, giving a clue to the nature of the disease. Port-wine nevus in the distribution of the fifth cranial nerve may be associated with hemangioma of the brain. A patient with a port-wine nevus of the face who has convulsions must be considered as probably having an angioma of the brain.

Telangiectatic hemangiomas occasionally are removable lesions. The bulk of angiomas are cavernous in nature, however, and are not amenable to surgical or roentgen therapy. Unequivocal localization and diagnosis of this group are often possible through the arteriogram. Since these tumors do not grow, the chief problem is that of control of the convulsions which so frequently are the only cause for complaint.

Hemangioblastoma.—The hemangioblastoma, a tumor of proliferating embryonic blood vessels, may occur in middle life. It usually is found in the posterior fossa, giving evidence there of a slowly progressive, expanding lesion. This tumor is often cystic, the neoplastic part being preserved as a mural nodule. It is susceptible to roentgen therapy to a moderate degree. There may be an associated angioma of the retina and cystic degeneration of the parenchymatous organs of the abdomen (Lindau's disease).

INTRACRANIAL GRANULOMA

Granulomas in the brain may produce symptoms indistinguishable from those of neoplastic growths. Tuberculosis is the one most commonly encountered nowadays. It may be calcified and in certain regions may be successfully excised. Though occasional gummas are still to be seen, meningovascular syphilis is a more frequent mimic of an intracranial tumor. The diagnosis is made by serologic studies, and treatment is antisyphilitic.

Since the Leyte campaign, several instances of granuloma from schistosomiasis japonica have been reported, the granuloma behaving in all clinical respects like an expanding neoplasm of the cerebrum. Excision coupled with appropriate systemic treatment has generally been satisfactory in control of the disease.

METASTATIC TUMORS

Malignant disease elsewhere in the body may metastasize to the brain. Sometimes the intracranial metastasis will be the first evidence of the mother tumor. Cancers in the thoracic cage, of retroperitoneal origin, and of the breast, and malignant melanoma are common sources of intracranial metastases. Cancers in the throat and neck may invade the cranium by direct extension and erosion.

When circumstances indicate a single cerebral metastasis and the mother tumor apparently is under control, extirpation of the cerebral metastasis may be justified. Metastatic tumors in the brain are usually surrounded by an area of necrotic cerebral tissue and often may be completely eradicated. They ordinarily produce little general reaction on the part of the brain, and the patient may recuperate with surprising rapidity. The uncomplicated survival for many months following extirpation of a single cerebral metastasis is most gratifying for all concerned.

CONGENITAL TOXOPLASMOSIS

B. H. KEAN, M.D.
and
ROBERT G. GROCOTT, B.S.
New York

Toxoplasmosis has been clearly recognized as a disease of human beings only in recent years, but the disease is apparently much more prevalent than has been appreciated. Various clinical and pathologic types, congenital, infantile, adult typhus-like, chronic and asymptomatic, have been described. Since excellent reviews of this rather complicated subject have been provided by Wolf, Cowen and Paige,¹ Sabin,² Weinman,³ Pratt-Thomas and Cannon,⁴ Zuelzer⁵ and, recently, Callahan, Russell and Smith,⁶ another summary of the literature would be superfluous.

REPORT OF CASE

Clinical Background.—On Oct. 6, 1945, the father brought to Gorgas Hospital an infant who had been delivered one and one-half hours earlier at home. The midwife, recognizing prematurity and stating that she had never seen such a "gray" placenta, insisted that the child be brought to the hospital.

6. Callahan, W. P., Jr.; Russell, W. D., and Smith, M. C.: Human Toxoplasmosis, *Medicine* 25: 343-397, 1946.

On admission no abnormalities other than prematurity were recognized; examination purposely was limited. The child was placed in an incubator. He became cyanotic, respirations were

Fig. 1.—Section of cerebral cortex showing intense inflammatory reaction. × 175.

Fig. 2.—Individual parasites in brain. × 1,400.

gasping and irregular, and the infant died nine hours after admission, ten and one-half hours after birth. There were no convulsions. The placenta that had been carefully brought in

with the child was rejected at the admitting office of the hospital and discarded.

The family, mother, father and their 20 month old son had lived for about ten months in Rio Abajo, a fairly well sanitized community about 7 miles (11.3 kilometers) from the City of Panama. Their house, of mixed wood and concrete construction, was located at the edge of the village not more than 50 yards (45.7 meters) from the "bush." Many less pretentious houses were in the neighborhood. Cats, dogs, goats, chickens, rats and pigeons were in the yard or close by. Mosquitoes were the bane of the neighborhood. No other insects were reported as troublesome, but most of the dogs were infested with *Rhipicephalus sanguineus*, the common dog tick. The family was admitted to the hospital for study.

The mother was a 24 year old Panamanian multipara. At the age of 16 years she had two abortions (each at three months), each by a different consort. Her next child (by the current husband) was now 20 months of age. The fourth was the infant with toxoplasmosis. Her last menstrual period started Feb. 18,

Fig. 3.—Section of fifth cranial nerve showing two nests of parasites. $\times 1,000$.

1945. She felt perfectly well during her pregnancy. On October 6 she went into labor, and "a few hours" later was delivered without difficulty. The puerperium was uneventful. Physical examination, routine hematologic studies, urinalyses, stool examinations, ophthalmologic examination, electrocardiogram and roentgenograms of the skull and chest revealed no abnormality. The Wassermann reaction of the blood was negative; the Kahn reaction was positive.

The father was a 30 year old Colombian mestizo, who had lived in Panama for five years. He had a history of gonorrhea, inadequately treated syphilis, and vague fever several years previously. In other respects, the personal history, family history, physical examination, roentgenograms of the skull and chest and an electrocardiogram revealed no abnormality. A small patch of healed chorioretinitis was found "at 6 o'clock near the periphery of the right eye." Wassermann and Kahn reactions of the blood were positive.

The 20 month old son was in excellent health. Complete examination of a type similar to that conducted on the father revealed no abnormality. His fundi were normal.

Necropsy.—Gross Examination: Permission for autopsy could not be obtained until thirty-one hours after death. During this period the body was kept in the refrigerator at a temperature of 32 to 38 F.

Fig. 4.—Intense choroiditis. $\times 175$.

Fig. 5.—Small nest of parasites in eye. $\times 1,400$.

The infant weighed 1,070 Gm. and measured 38 cm. from vertex to heel. The estimated intrauterine age was $6\frac{1}{2}$ to 7 months. The head appeared somewhat smaller than usual,

but its circumference was not measured. The fontanelles were flat.

When the calvarium was removed much bloody cerebrospinal fluid gushed forth. (In a test tube, after an hour, a thick layer of white, yellow and gray granular material settled to the bottom. The supernatant fluid was reddish brown and turbid.)

Fig. 6.—Section of spinal cord showing symmetric calcification. $\times 8$.

Fig. 7.—Nest of parasites in spinal cord. $\times 1,400$.

The brain was a collapsed, gelatinous, almost shapeless mass which lay on the floor of the middle cranial fossa and was covered by hemorrhagic leptomeninges, in portions of which yellowish zones were seen. On removal, the cerebrum was so soft that it could hardly be handled, and no statement can be made concerning the convolitional pattern. The tissue was

pale, but flecked with conspicuous firm yellow granules. The cerebellum could not be identified even after long search.⁷ The brain stem was firmer, and the pons and medulla were recognizable as such. The spinal cord was soft, but its identifying landmarks were discernible. Sectioning of the pons, medulla and cord disclosed gritty, yellowish areas, averaging 0.2 cm. to 0.3 cm. in diameter; they showed a tendency to symmetry in location. The pituitary was of average size. The pattern of the skull appeared normal.

The lungs were atelectatic. All other organs seemed normal on gross examination.

Histologic Examination (the table): Brain. Scattered in the cortex and brain stem were many areas of focal necrosis with an intense granulomatous inflammatory reaction featuring an infiltration of macrophages, lymphocytes and plasma cells. In the areas of necrosis was an extensive deposition of calcium salts that could be demonstrated beautifully by the von Kossa stain. In the brain stem the zones of necrosis tended to be symmetric, but in the cerebral hemispheres no pattern could be discerned and in some areas there was a diffuse inflammatory

Fig. 8.—Nest of parasites in glomerular tuft. $\times 1,200$.

reaction in addition to the focal one. A moderately intense leptomenigitis was present and some blood pigment was noted in macrophages scattered in the meshes of the pia-arachnoid. Toxoplasmas disposed singly, in small groups and in pseudocysts were found without prolonged search. The individual parasites averaged 5 microns in length and 1 micron in width. In the spinal cord the inflammatory reaction was slight, but the parasites were seen in sections from cervical, thoracic and lumbar levels.

Eye. An intense granulomatous chorioretinitis was present. Parasites were few and could be found only after prolonged search, as small cystlike aggregates of three or four toxoplasmas.

Optic nerve. No parasites were seen, although an inflammatory reaction was present.

Fifth cranial nerve. Many toxoplasmas and an intense inflammatory reaction were seen.

7. How much of the necrosis and collapse of the cerebral hemispheres was ante mortem and how much was post mortem was difficult to ascertain. The absence of cerebellum and the fact that in many instances in which autopsies had been done on infants in similar circumstances no such complete collapse had been seen suggested strongly that most of the changes were ante mortem.

Lungs. Moderate atelectasis and a slight inflammatory reaction were noted. No parasites were found. Evidence of congenital syphilis was not recognized.

Heart. A barely recognizable diffuse inflammatory reaction was present. No parasites were seen.

Liver. No parasites were noted. There was no evidence of congenital syphilis.

Kidneys. Caught within glomerular tufts were a few small nests of toxoplasmas that had excited no inflammatory reaction.

Bladder. In the lamina propria of the mucosa and in the muscular layers was a diffuse inflammatory reaction. Several small nests of toxoplasmas were found in nerve bundles.

Mammary gland. No parasites were seen in a section of the gland. In the adjacent skeletal muscle toxoplasmas were present.

Parotid gland. The glandular elements appeared normal. In adjacent skeletal muscle toxoplasmas were seen.

were injected into the peritoneal cavity of guinea pigs but failed to infect them. No toxoplasmas were seen in thick

Fig. 9.—Nest of parasites in bladder. $\times 1,400$.

Tongue. Several groups of toxoplasmas were present. The inflammatory reaction was moderate.

Skeletal muscle (leg and back). Toxoplasma pseudocysts were relatively numerous.

Femoral nerve. Many toxoplasmas and an intense inflammatory reaction were present.

Thymus, thyroid, spleen, pancreas, adrenal glands, intestine, lymph nodes, bone marrow and umbilical cord. No lesions or parasites were seen.

Experiments.—**Infant:** Guinea pigs inoculated intraperitoneally with emulsions of brain suspended in the hemorrhagic spinal fluid died in ten days. Toxoplasmas were easily demonstrated in the peritoneal exudate, in the brain and many other organs of these guinea pigs. Toxoplasmas recovered from these pigs were lethal on subinoculation to other guinea pigs, and the strain was carried through several series of guinea pigs. (It is of interest that the parasites were viable after thirty-one hours in the refrigerator at a temperature of 32 to 38 F.)

Mother: Spinal fluid, venous blood, cervical and vaginal washings, all taken from the mother ten days after delivery,

Fig. 10.—Nest of parasites in skeletal muscle of tongue. $\times 350$.

Fig. 11.—Nest of parasites in skeletal muscle of leg.

films of this material or in her breast milk. No parasites were found in 150 sections of a biopsy of her deltoid muscle taken

at the same time. An emulsion prepared from crushed deltoid muscle was injected into guinea pigs, and produced no infection.

Father: Venous blood failed to infect guinea pigs inoculated intraperitoneally. No parasites were seen in thick films of his prostatic fluid.

COMMENT

Pratt-Thomas and Cannon⁴ listed 20 previously noted cases of toxoplasmosis confirmed by autopsy and added 1 of their own. Callahan, Russell and Smith⁵ recently added 5 cases in infants. The case reported here, the 27th, is the twenty-seventh proved by necropsy and the twenty-first in an infant. This is the first proved case of congenital toxoplasmosis on the Isthmus of Panama, although 5 other cases of toxoplasmosis have been seen.⁸

The absence of any symptoms of the disease in the mother was perplexing as usual. It is reasonable to assume that the infection of the fetus occurred rather late in the pregnancy, and yet the mother remembered no illness. Efforts to demonstrate a latent infection in maternal body fluids and skeletal muscle were unsuccessful.

The number of organs involved in this and other cases⁹ indicated that toxoplasmosis is a systemic disease with a predilection for the central nervous system but the ability to appear in almost any organ. The parasitization of nerves (fifth, cranial, femoral and nerves in bladder) has not been described previously in human beings to the best of our knowledge. Johnson,¹⁰ however, recorded extensive involvement of nerves in toxoplasmosis in pigeons.

The widespread incidence of toxoplasmosis in animals¹¹ and the relative lack of host specificity of the parasite suggest that human infection occurs by transmission of the disease from an animal reservoir. Although transmission may be direct, the possibility of the existence of an insect vector must be considered. Since the disease has been described in various parts of the world, it is unlikely that either the animal reservoir or the insect vector—if they exist—is exotic. On the basis of very little evidence we would like to suggest the possibility that pigeons may play an important role. Johnson¹⁰ described an epidemic of toxoplasmosis in carrier pigeons in the Canal Zone, and pigeons were noted close to the home of the patient described in the current case report. These birds were also seen in the neighborhood of the homes of 2 patients with asymptomatic toxoplasmosis on the Isthmus of Panama. (Departure of one of us, B. H. K., from the Canal Zone prevented further investigation of this possibility.) Mosquitoes might qualify as a vector.

Parenthetically, the occurrence of severe congenital encephalomyelitis in another male infant, stillborn after six months of intrauterine life, should be mentioned. In this infant, the cerebral hemispheres were small, soft, collapsed and covered by reddish brown leptomeninges. Histologically an intense granulomatous inflammatory reaction similar to that seen in the current case of toxoplasmosis was present. Parasites were not demonstrated, however, either visually or by guinea pig inoculations; nevertheless we believe that this might well represent a "burnt-out" case of toxoplasmosis.

SUMMARY

A case of toxoplasmosis, the twenty-seventh authenticated by autopsy, the twenty-first in an infant and the first of the congenital type on the Isthmus of Panama, is reported. Parasites were found in the brain, spinal cord, eye, fifth cranial nerve, femoral nerve, kidney, urinary bladder nerves and skeletal muscles of the tongue, cheek, chest, leg and back. Attempts to demonstrate a latent infection in the mother were unsuccessful. On extremely tenuous grounds the possibility is suggested that pigeons may act as an animal reservoir.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports. HOWARD A. CARTER, Secretary.

IMPROVED NEBULIZER PREMO
ACCEPTABLE

Manufacturer: Premo Pharmaceutical Laboratories, Inc., 443 Broadway, New York 13.

The Improved Nebulizer Premo is a device, mainly of glass, for projecting liquids, especially aqueous solutions, as extremely fine mists, or aerosols. This makes it possible to administer by inhalation nonvolatile medicaments, like epinephrine and penicillin. The construction of the device is such that practically all of the liquid placed in it may be nebulized.

Improved Nebulizer Premo.

The Council on Pharmacy and Chemistry has accepted a preparation of penicillin for administration by this method. There is evidence that a patient who inhales, for instance, 50,000 units of penicillin will show a concentration of 0.1 to 0.2 units of penicillin per cubic centimeter of serum for a period as long as two hours after the inhalation.

Because of the fineness of the division of the nebulized liquid, the process of administration is not fast. One cubic centimeter of water required four and one-half minutes to be completely nebulized when compressed air was used and required seven minutes by manual employment of the rubber bulb.

The Council voted to include the Improved Nebulizer Premo in its list of accepted devices.

OTARION HEARING AID MODEL E1,
ACCEPTABLE

Manufacturer: Otation Hearing Aids, 448 North Wells Street, Chicago 10.

This instrument is a self-contained hearing aid, with the battery compartment at the lower end of the case. The case is a die-cast magnesium alloy, coated with Vinyl Resin finish. A side-hinged full-length back cover gives access to the batteries and the two tubes, which are not covered. One magnetic type receiver is used and is connected to the amplifier by means of a plastic-covered cord with plugs at both ends.

Two wheel-type controls are placed on the top of the case. One is a volume control. The other is a combination on-off tone control having an off position and three tone positions. A detachable wearing clip fastens to the back of the case.

Dimensions and Weight

Dimensions: 130 by 67 by 22 mm. (5 $\frac{1}{8}$ by 2 $\frac{5}{8}$ by $\frac{7}{8}$ inch).

Weight: Approximately 219 Gm. (7 $\frac{1}{2}$ ounces) (with batteries).

Battery Drain Data	Measured Voltage	Measured Current
A, zinc and carbon, 1.5 volts.....	1.3 volts	55 milliamperes
B, zinc and carbon, 30 volts (Quiet)....	29 volts	0.46 milliamperes
(Squealing)	29 volts	0.4 milliamperes

Acoustical Gain

Measurements were made of the acoustical gain in decibels (sound pressure in 2 cc. coupler in decibels above sound pressure at microphone, with microphone set in 30 by 20 cm. baffle) with the input level held at 0.02 dyne per square centimeter.

The following tabulation gives typical results obtained with the volume control full on, for two settings of the tone-control at each of seven frequencies:

Frequency	256	512	1,024	1,200	2,250	3,100	4,096 cycles
Tone: 1 dot.....	33	36	41	51	40	32	17 db.
Tone: 3 dots.....	22	30	41	50	40	32	17 db.

Approximate values of maximum sound pressure levels at four frequencies observed in the 2 cc. coupler with volume set for full gain and tone setting "1 dot" are shown below:

Frequency	Input Level	Maximum Output Level
600 cycles	65 decibels	103 decibels
1,024 cycles	70 decibels	111 decibels
1,200 cycles	70 decibels	114 decibels
2,048 cycles	65 decibels	100 decibels

Intelligibility tests (random words) were made with a person of normal hearing seated inside a booth giving about 30 decibels sound reduction. The speaking person was outside the booth using a normal tone of voice. Score made under these critical conditions was 40 per cent. The instrument was quiet, but low amplification caused the low score. It appeared that the instrument would be satisfactory for subjects requiring moderate amplification. It could not be recommended in severe cases of deafness.

On the recommendation of the Consultants on Audiometers and Hearing Aids, the Council on Physical Medicine voted to include the Otation Hearing Aid, Model E1, in its list of accepted devices.

PARAVOX HEARING AID, MODEL XTS, ACCEPTABLE

Manufacturer: Paraphone Hearing Aid, Inc., 2056 East Fourth Street, Cleveland 15.

This self-contained hearing aid comes in a plastic-coated metal case, with the battery compartment at the lower end of the case. Access to the batteries is made possible by a sliding cover plate half the length of the instrument. The amplifier remains well protected in the upper half of the case when the battery cover is removed. A crystal type receiver is connected to the amplifier by means of a 76 cm. (30 inch) plastic covered cord, with plugs at each end.

Paravox Hearing Aid,
Model XTS.

There are two wheel-type control knobs on the top of the instrument, one to regulate the volume and the other to select the tone (three positions) and turn off the aid. A wearing clip is

fastened to the front of the case directly above the microphone.

Dimensions and Weight

The dimensions are 127 by 63 by 19 mm. The weight (with batteries) is approximately 173 Gm. (6 ounces).

Battery Drain Data	Measured Voltage	Measured Current
A: Zinc-carbon, 1.5 volts.....	1.4 volts	40.00 milliamperes
B: Zinc-carbon, 30 volts (Quiet)....	29.0 volts	0.60 milliampere
(Squealing).....	29.0 volts	0.60 milliampere

Acoustical Gain

Measurements were made of the acoustical gain in decibels (sound pressure in 2 cc. coupler in decibels above sound pressure at microphone, with microphone set in 30 by 20 cm. baffle) with input level held at 0.02 dyne per square centimeter.

The following tabulation gives typical results obtained with the volume-control full on, for two settings of the tone control at each of seven frequencies:

Frequency.....	256	512	1,024	1,200	2,250	3,100	4,096 cycles
Tone: 1 dot.....	45	58	66	69	48	61	58 decibels
Tone: 3 dots.....	30	43	52	55	29	38	35 decibels

Approximate values of maximum sound pressure levels at four frequencies set up in the 2 cc. coupler were determined with the volume set for full gain and tone setting at one dot:

Frequency	Input Level	Maximum Output Level
600 cycles	60 decibels	114 decibels
1,024 cycles	60 decibels	120 decibels
1,200 cycles	60 decibels	123 decibels
2,048 cycles	60 decibels	103 decibels

Intelligibility tests of random words were made with a person of normal hearing seated inside a booth giving about a 30 decibel reduction in sound. The speaking person was outside the booth using normal speaking voice. The score made under these critical conditions was 61 per cent.

On the recommendation of the Consultants on Audiometers and Hearing Aids, the Council on Physical Medicine voted to include the Paravox Hearing Aid, Model XTS, in its list of accepted devices.

MICROTONE AUDIOMATIC HEARING AID MODEL T4 ACCEPTABLE

Manufacturer: The Microtone Company, 4602 Nicollet Avenue, Minneapolis 9.

The Microtone Audiomatic Hearing Aid, Model T4, is a plastic-cased, self contained instrument with the battery compartment at the lower end of the case. Half of the back is removable for access to the battery and is secured by a snap catch. A crystal receiver is connected to the instrument by a plastic-covered cord.

A three position lever switch at an upper corner of the instrument has an off position and two tone positions. The wheel-type volume control is at the other upper corner of the case. The wearing clip is at the center on the front of the case.

Dimensions and Weight.—Dimensions 127 by 64 by 25 mm. Weight (with batteries) 255 Gm. (9 ounces).

Batteries (Zinc and Carbon)	Measured Voltage	Measured Current
A 1.5 volts.....	1.3 volts	46 milliamperes
B 30 volts (Quiet)....	29 volts	0.4 milliampere
(Squealing)	29 volts	0.5 milliampere

Microtone
Audiomatic
Hearing Aid
Model T-4

Acoustical Gain.—Measurements were made of the acoustical gain of the instrument in decibels. This is the decibel difference in sound pressure between the pressure at the face of the microphone opening (with instrument set in 40 by 20 cm. baffle) and the pressure produced by the receiver in a 2 cc. coupler. The microphone sound pressure was held at a level 40 decibels above 0.0002 dyne per square centimeter. Following is a tabulation of typical results in decibels:

Frequency	256	512	1,024	1,200	2,250	3,100	4,096
Tone-control "up".....	30	41	54	57	49	47	43
Tone-control "down"....	25	32	51	55	44	45	38

Maximum Output Pressure.—Measurements were made of the approximate maximum sound pressures the instrument would produce in the 2 cc. coupler with the instrument set for full gain and "up" tone position. Levels are in decibels relative to 0.0002 dyne per square centimeter. Results are shown below:

Frequency	Input Level	Maximum Output Level
600 cycles	65 decibels	107 decibels
1,024 cycles	65 decibels	117 decibels
2,048 cycles	65 decibels	102 decibels
2,750 cycles	65 decibels	111 decibels

Intelligibility tests (random words) were made with a person of normal hearing seated inside a booth giving a sound reduction of about 30 decibels. The speaking person was outside the booth using a normal tone of voice. The score made under these critical conditions was 30 per cent. Instrument background noise caused the low score. A deafened person should attain much better results.

On the recommendation of the Consultants on Audiometers and Hearing Aids, the Council on Physical Medicine voted to include the Microtone Audiomatic Hearing Aid, Model T-4, in its list of accepted devices.

THE ETIOLOGY OF APICAL SCARS

Fibrous scars accompanied regularly by local anthracosis and emphysema and sometimes by fibrotic, caseous or calcific nodules are commonly found at necropsy in the apexes of one or both lungs. These have long been accepted as tuberculous scars. This interpretation has recently been challenged by Medlar,¹ whose data warrant critical examination before the old concept is discarded.

Medlar analyzed data on 1,400 necropsies in cases of unexpected death in the Medical Examiner's Department of the Borough of Manhattan. Of this number, 141 were excluded from further consideration because of extensive pleural or pulmonic disease. The 1,259 remaining cases, in which 960 subjects were white and 299 were Negro, were analyzed according to race, age and apical scars in relation to presence or absence of tuberculous lesions. Calcified or caseous foci or tuberculous cavity in the lung, or similar lesions elsewhere, were accepted as diagnostic of tuberculosis.

Apical scars were present in 48.1 per cent of white subjects who had evidence of tuberculosis and in 31.9 per cent of those without tuberculous lesions; the corresponding figures for Negroes were 14.7 and 8 per cent. The apical scars were related to age; none were found in 106 persons under 20 years of age; 65.9 per cent of 290 persons over 60 years of age had scars. The corresponding figures for tuberculous lesions in these two groups were 21.7 and 88 per cent. The apical scars were commoner in white persons than in Negroes at corresponding ages, and commoner in men than in women. They were bilateral in 97.2 per cent. Tuberculous foci were found contiguous to or in apical scars in 33 cases. In addition, 20 persons who had apical tuberculous lesions had no apical scars. Forty-five persons had apical tuberculous lesions but were excluded from the analysis because they had dense pleural adhesions.

Two separate questions are at issue: (1) Are the apical scars tuberculous and, if so, (2) are they the result of a postprimary hematogenous dissemination of tubercle bacilli or of infection by some other method?

Rejection of the tuberculous causation for the apical scars was based on five points: (a) Apical scars occurred as frequently in persons without evidence of tuberculous lesions as they did in those with tuberculous foci. (b) The bilateral and symmetric pattern of the apical scars bore no resemblance to the asymmetric and scattered distribution of the tuberculous lesions. (c) Tuberculous lesions occurred in the apex with or without apical scars being present. (d) Apical scars occurred in lower lobes only when they occupied an apical position, although tuberculous foci were found in the upper portion of the lower lobes when they occupied their normal site. (e) The differences noted in relation to sex and race were not accounted for by acceptance of a tuberculous etiology.

The incidence of tuberculous lesions (75.2 per cent in whites and 61.5 per cent in Negroes) was considerably less than that recently reported from Baltimore² (90 per cent) and from Chicago³ (88.8 per cent). This may indicate that some tuberculous lesions were overlooked; special methods of detection were not used as in the latter two reports. The data in table 1 of Medlar's article show a parallelism between the incidence of apical scars and tuberculous lesions. Thus, 48.1 per cent of white persons with tuberculous lesions had apical scars and only 31.9 per cent of those without tuberculosis had the scars. The figures for Negroes were similar although lower. The bilateral and symmetric pattern of the apical scars in contrast to the asymmetric and scattered distribution of the tuberculous lesions does not disprove the tuberculous nature of the former. Many of the latter, no doubt, were the residues of primary infections which are known to be widely scattered in the lungs. Some of the tuberculous lesions in the apex without accompanying scars might, on microscopic examination, be found to be evolving to apical scars. Factors of time, resistance, exact site of infection and proximity of the lesion to the pleura might determine the type of anatomic lesion which would eventually result. The observation that apical scars occur in the apexes of lower lobes when they are elevated to form part of the dome of the lung speaks for a common etiologic basis rather than a different one. The sex difference in incidence of apical caps parallels, although at a lower level, those seen in tuberculous lesions. Factors of resistance or susceptibility might explain the differences noted in the racial groups as well as in the sexes.

2. Carnes, W. H.: The Present Incidence of Tuberculous Infection, *Bull. Johns Hopkins Hosp.* 70: 101 (Feb.) 1942.
3. Steiner, P. E.; Stanger, D. W.; Bolyard, M., and Marcovitch, A. W.: The Quantity of Focal (Tubercle) Calcium in Human Lungs, *Am. Rev. Tuberc.* 49: 129 (Feb.) 1944.

The theory that the apical scars are the result of a postprimary hematogenous dissemination of tubercle bacilli was rejected because it did not explain the presence of bilateral apical scars in cases which exhibited no tuberculous lesions. Perhaps tuberculous lesions in these cases had virtually disappeared or, as has been suggested, had been overlooked.

Careful consideration must be given to definition of the apical scar. Is it to be defined in the restricted sense of an anthracotic, fibrous scar confined to the pleura, or may it include also diffuse fibrous and even nodular caseous and calcific lesions immediately beneath the pleura? On microscopic sections made through the apex a clearcut distinction is often impossible; the lesions merge into each other with respect to location, histologic type and stage of evolution. Scars in the apical pleura frequently show evidence that subjacent pulmonic tissue together with its lesions has been retracted and incorporated into the scar.

Possibly this problem cannot be solved by statistical methods, but it might yield to morphologic or experimental studies.

EXOTIC DISEASES

In this issue of *THE JOURNAL*, page 81, appears a case report by Levy and Yiengst¹ of kala-azar in New York City. This patient had been away from endemic areas of visceral leishmaniasis for seventeen to nineteen months, an incubation period not unusual in this disease. Preliminary physical examination revealed vague abdominal tenderness, loss in weight, fever and mild reddening of the pharynx but was otherwise negative. Observations of this sort might easily indicate any one of many other maladies common to the United States. Fortunately in this case the necessary medical curiosity combined with excellent laboratory facilities determined correct diagnosis and provided for proper treatment.

Without typical symptoms, differential diagnosis included consideration of malaria, leukemia, bacillary dysentery, typhoid, paratyphoid, undulant fever, typhus, tularemia and others. Diagnosis became apparent only after the second biopsy of bone marrow. Adequate laboratory facilities such as are implied in the foregoing account are not available to all practicing physicians in this country. Nevertheless exotic disease must now be constantly suspected.

In World War II several million Americans were transported beyond the limits of the United States, many hundreds of thousands to areas where tropical disease and diseases foreign to this country are endemic. Moreover, postwar civilian and military travel to these areas has greatly expanded.

Meleney,² Sawyer,³ Mackie,⁴ Faust⁵ and many others have warned repeatedly of the danger of tropical disease occurrence in the United States. Diseases probably most frequently met will be malaria, bacillary dysentery, amebiasis, filariasis and intestinal protozoan infestations. These will be seen in areas where they were formerly rarities or nonexistent. Others, such as kala-azar, African and South American trypanosomiasis, cutaneous leishmaniasis, schistosomiasis, yaws and pinta will occur in scattered numbers. Prevalence of leprosy in areas where troops were stationed makes appearance of a few cases after long incubation periods almost inevitable.

Velocity plane travel which allows passengers to travel half around the world from home to destination within the intervals of short incubation periods in part nullifies usual quarantine methods and may allow entrance of patients with yellow fever, plague, cholera and epidemic typhus. Authorities in international health work have indicated that protection for the United States demands lowering of the incidence or stamping out of these communicable diseases in the endemic areas of the world. Effective work of this nature is now being done by the Rockefeller Foundation and in this hemisphere by the Health and Sanitation Division, Institute of Inter-American Affairs.

Most exotic diseases do not constitute epidemic or endemic hazards in the United States because known vectors or intermediate hosts are lacking and high standards of community sanitation prevail. The possibility exists, however, that new appropriate vectors and intermediate hosts may develop and that more virulent strains of the pathogens now common to this country may be imported.

Despite all epidemiologic considerations these diseases are immediate problems to the practicing physician. Proper cure of the patient and primary protection of the community will depend on the physician's diagnostic ability. Accurate typical clinical pictures are given by Strong⁶ and other authors. However, many of the diseases mentioned, such as amebiasis, schistosomiasis, malaria and Chagas' disease, having passed through the acute stage and entered on a mild intermediate or chronic stage, present themselves in the patient in masked form. Symptoms are frequently vague, such as fatigue, recurrent headache, loss in weight, nervousness, palpitation and uneasiness with mild to moderate gastrointestinal distress. In view of the added stress placed in recent years on the

psyche and the fact that these same symptoms are frequently met in psychoneurotic patients, differential diagnosis becomes doubly interesting, challenging and difficult.

Current Comment

ADVERTISING AIDS TUBERCULOSIS CAMPAIGN

Early in 1948 the Advertising Council, Inc., will be sponsoring a "Check Tuberculosis" campaign. The project has been undertaken in cooperation with the National Tuberculosis Association, its state and local affiliates, and the U. S. Public Health Service. The purpose of this campaign is educational. During the war the Advertising Council, Inc., aided the government in its campaigns for the sale of war bonds, for recruitment of nurses and in many health projects. Now all various advertising technics will be utilized to emphasize the importance of early diagnosis in tuberculosis and to urge people to have the chest examined with the roentgen ray periodically. Tuberculosis is the first disease to be selected by the Advertising Council, Inc., as a target for a campaign, the reason being that we now possess the necessary technics and methods to eliminate this disease if only all the forces available can be mobilized against it.

EXPERIMENTAL STUDY OF STREPTOMYCIN DOSAGE IN TUBERCULOSIS

On the basis that streptomycin acts as an "antiseptic" chemical retardant, dosage has been computed on the assumption that the action of streptomycin in vitro is dependent on direct concentration and in vivo is likewise dependent on the concentration apparently reaching the tubercle bacillus. Toxic symptoms from the use of streptomycin in man were considered unavoidable. Recent observations in animals, on which such tests can be performed in a controlled manner, reveal that streptomycin produced the same effects in prolonging the lives of these animals against an otherwise lethal infection when given once in five days as when given every day. This is called the "remote sustained threshold action" of streptomycin¹ and includes all its implications as far as treatment of tuberculosis is concerned, even though it is admitted that the apparent action of streptomycin is neither clearly nor fully understood at present. However, one fact appears certain: Whatever beneficial effect streptomycin has on human tuberculosis may be obtained without forcing the use of this antibiotic to the point of injury to the patient. An adequate proving ground for claims that streptomycin used may benefit the tuberculous patient has been established; the history of the tubercle bacillus rise and fall with each treatment. The mental scientific information needed—alleged therapeutic effect of streptomycin in tuberculosis—urgently needed—and

FLUORINE AND DENTAL CARIES

Since fluorine was discovered in drinking water¹ and identified as the causative agent for mottled enamel,² many reports have appeared showing the widespread distribution of areas of endemic fluorosis. The positive correlation between a concentration of fluorine in potable water of 1 part per million or more and mottled enamel of the teeth of children consuming this water since early infancy has been established. However, the fact that fluorine may have an other than deleterious effect on the teeth of children was first suggested in this country by Dean,³ who commented on the rarity of dental caries in those areas where endemic fluorosis exists. Later,⁴ on the basis of dental examinations of over 7,000 children in twenty-one cities, the conclusion was reached that there exists a general inverse relationship between the fluorine in the drinking water and the caries rate in children continuously consuming the water throughout life. Moreover, Klein⁵ reported that this influence of fluorine can be demonstrated in children who have been exposed to drinking water containing this element for the first time, after reaching school age. There are indications⁶ that the inhibiting effects of fluorine on dental caries can be demonstrated for a long time after removal of the element from the water supply. Furthermore, the suppression of the count of *Lactobacillus acidophilus* likewise endured. This organism was early implicated⁷ in the causation of dental caries; later it was shown⁸ that fluorine in such concentrations as occur in some potable waters suppresses acid production by the organism though not necessarily inhibiting its growth. A study of the available evidence led McClure⁹ to state that from 0.5 to 1 part per million of fluorine in the drinking water is instrumental in reducing caries and that the evidence does not indicate that this constitutes a health hazard. The neighboring cities Newburgh and Kingston, N. Y., both originally used water low in fluorine. In 1944 the addition of 1 part per million of fluorine to the water supply was begun in Newburgh but not in Kingston. Recently, a report¹⁰ compared the acidophilus count in the saliva of a large number of children 12 to 14 years of age in both cities with that before the experiment was begun. In Kingston the frequency of high and low counts remained in 1947 as it was in 1944; in Newburgh a progressive drop in the frequency of high counts and an increase in the proportion of low counts had occurred, thus indicating results in the direction of suppressing the acid-producing organisms in the mouth. Additional significant data are eagerly awaited from this study; further favorable results will mark progress in conquering a most vexing medical problem.

A CABINET DEPARTMENT OF HEALTH, EDUCATION AND SECURITY

GERHARD HIRSCHFELD
Director of the Research Council for Economic Security
and

E. M. WOOD
Research Assistant
Chicago

(This article has been approved by the Bureau of Legal Medicine and Legislation of the American Medical Association.)

Overshadowed by more spectacular legislation, the proposal to create a cabinet department to administer the health, education, public welfare and social security functions of the federal government has received little attention. A bill for this purpose, S. 140, was introduced early in the 80th Congress by Senators Fulbright and Taft. The proposal is in line with the steady increase in federal participation in fields which have in the past been largely the concern of state and local agencies. The bill in itself adds no new federal functions and grants no new authority, but it would add prestige to existing functions by giving them status in the highest level of government: the President's cabinet. In this connection it may have great potential significance.

STATE AND FEDERAL RELATIONSHIPS IN HEALTH, EDUCATION AND SECURITY

The Constitution gives Congress and the federal government the power "to promote the general welfare," but it has been generally understood that health, education and security functions are left for the most part to state and local authorities. Under the general welfare clause the federal government has gradually increased its activities in social fields in a rather haphazard, largely unplanned fashion. Legislation for this purpose tends to take two major forms, (1) expanding services performed by federal agencies and (2) increasing federal participation by grants-in-aid to the states for designated uses. Usually the promise of federal funds has been conditioned on requirements for matching state and/or local expenditures. Indeed, federal legislation has often had the deliberate purpose of stimulating state expenditures which probably would not have been made without this incentive. As a result, both state and federal governments have steadily increased their functions in health, education and security fields, and there is no evidence of any change in this trend.

The result of a succession of piecemeal legislation is that the relationship between federal and state-local responsibility has become hazy. It is not clear where local responsibility leaves off and federal responsibility begins. While the states tend to be jealous of federal encroachment, at the same time they are glad to receive federal funds. It may be worth while to consider briefly the present status of federal-state relationships in these activities.

WHAT IS THE PRESENT ROLE OF THE FEDERAL GOVERNMENT?

In the field of education state and local jurisdictions still carry the major share of responsibility. The federal role, although increasing, is still relatively minor. It is possible that federal participation in education may increase further, particularly in the poorer states which have yet to provide adequate educational facilities for their students. So far, how-

ever, federal activities in education are confined largely to compilation of school statistics, research and advisory services, and to grants-in-aid to states and private institutions for limited special purposes, such as vocational education, training of handicapped persons and scientific research (chart 1).

The federal role is greater in the field of health. There is, of course, an extensive federal medical program for the military services and veterans, but the U. S. Public Health Service is the major agency providing health services for the general public. While this agency is primarily concerned with research and disease prevention, successive legislation has increased its scope of activities for specific health problems: venereal disease, cancer and tuberculosis control, mental illness, hospital construction, etc. In addition, the Children's Bureau has health functions relating to problems of children, notably the administration of federal grants for maternal and child health, child welfare and services to crippled children. While the states have expanded their health services, they have come to be increasingly dependent on grants from the Public Health Service and the Children's Bureau (chart 2).

However, it is in the field of public assistance and social security that the federal government looms largest in the picture. Under the Social Security Act of 1935 the states were induced by the promise of federal matching grants to adopt or extend "categorical" programs of public assistance: old age

Chart 1.—Governmental expenditures for education by source of funds and fiscal years. The proportion of expenditures for educational purposes coming from federal funds has been increasing, but the federal role is still a minor one. Source: U. S. Office of Education, Statistical Summaries of Education for 1935-1936, 1939-1940 and 1943-1944.

assistance, aid to the blind and aid to dependent children. Total costs for these programs have mounted steadily, and the proportion of federal to state and local funds has risen from about 44 per cent in 1939 to 53.5 per cent in fiscal 1946-1947. The absolute and relative rise in federal funds has occurred even though in recent years the states have been strong financially, while the federal government has incurred a tremendous public debt. Federal control over funds expended through state public welfare agencies is concerned with standards of assistance and administration. While the states have sometimes chafed under these controls, they nevertheless have demanded and obtained continuing increase in federal funds (chart 3).

In the case of other social security programs the picture is confusing. Old age and survivors insurance is completely federalized; the states have no part in it. On the other hand, the states administer unemployment compensation, although the original inducement to adopt this program came from the Federal Social Security Act. Unemployment benefits are paid from state trust funds, but the cost of administration is borne by federal grants. In the case of the railroad workers the picture is again a different one. Both railroad retirement and railroad unemployment and disability benefits are federalized; administration of these programs is in the hands of the U. S. Railroad Retirement Board (table 1). Another major program in a somewhat related field—that of pensions and services for

veterans—is also federalized, although some states have their own veteran programs and a few states pay bonuses or pensions to veterans.

HISTORICAL BACKGROUND OF THE PROPOSAL FOR A CABINET DEPARTMENT

Proposals for a cabinet department for health, education and social welfare functions of the federal government antedate many of the now existing functions in these fields. An early proposal was made in the administration of President Harding, but Congress did not take action at that time. Subsequently, President Hoover sponsored a consolidation of certain federal social activities into a major division of the Department of Interior, under the supervision of an assistant secretary. Again Congress failed to act. With the advent of President Roosevelt's administration in 1933, federal relief, health, educational and other welfare expenditures expanded rapidly. How-

PRESENT PROPOSALS FOR A CABINET DEPARTMENT

In his message to Congress accompanying the reorganization plan of 1946, President Truman said:

" . . . The size and scope of the Federal Security Agency and the importance of its functions clearly call for departmental status and a permanent place in the President's Cabinet. In number of personnel and volume of expenditures the Agency exceeds several of the existing departments. Much more important, the fundamental character of its functions—education, health, welfare, social insurance—and their significance for the future of the country demand for it the highest level of administrative leadership and a voice in the central councils of the executive branch.

"Accordingly, I shall soon recommend to the Congress that legislation be promptly enacted making the Federal Security Agency an executive department, defining its basic purpose,

TABLE 1.—Federal and State Financing of Social Security and Public

ever, the pressure of the economic emergency was such as to push the cabinet proposal into abeyance for the time being, while independent agencies were established to carry out welfare programs. The emergency relief and work relief agencies, of which the most important were Federal Emergency Relief Administration, Works Progress Administration, National Youth Administration, Civilian Conservation Corps and Public Works Administration, have now been disbanded.

During the latter part of the thirties there began a process of consolidation of the remaining health, education and welfare agencies, and under the Reorganization Act of 1939 the Federal Security Agency was created. Within the Federal Security Agency were grouped the Office of Education, the Public Health Service, the Social Security Board, the Food and Drug Administration and the Office of Vocational Rehabilitation. Further additions followed the reorganization plan of 1946. The Social Security Board was reconstituted the Social Security Administration; most of the Children's Bureau was taken from the Department of Labor, and the vital statistics functions of the Census Bureau were added to the Federal Security Agency. Table 2 shows the present units, personnel and expenditures by the Security Agency.

and authorizing the President to transfer to it such units and activities as come within that definition. . . ."

Subsequently, several bills were introduced in Congress to carry out the President's suggestions. Two alternative Senate Bills, S. 140 (Fulbright-Taft Bill) and S. 712 (Aiken Bill) were the subject of hearings in February and March, 1947, before the Senate Committee on Expenditures in Executive Departments. After some amendment, S. 140 was reported out to the floor favorably by the committee. In its report to the Senate, the committee said it " . . . is of the opinion that under a departmental set-up the increasingly important functions of the various activities now incorporated in the Federal Security Agency can be brought into closer accountability to the President and to the Congress, and promote increased economy and efficiency in their operations. . . ." The bill is now ready for discussion and action by the Senate when Congress reconvenes for the second session.

PROVISIONS OF THE FULBRIGHT-TAFT BILL

The Fulbright-Taft bill, S. 140 (table 3) calls for a federal Department of Health, Education and Security, headed by a Secretary of Health, Education and Security. There are to be

three major divisions of the department, each headed by an under secretary. The Under Secretary for Health is to supervise the Bureau of Health; the Under Secretary for Education, the Bureau of Education, and the Under Secretary for Public Welfare, the Bureau of Public Welfare. The bill gives the department no additional functions or authority, but merely lists functions authorized by prior legislation.

Certain transfers are specifically provided. To the Bureau of Health will go the U. S. Public Health Service, the Food and Drug Administration, Freedmen's Hospital and Saint Elizabeths Hospital. To the Bureau of Education will go the U. S. Office of Education, Howard University, the American Printing House for the Blind and the Columbia Institution for Deaf. To the Bureau of Public Welfare will go the Social Security Administration, which in volume of expenditures is by far the most important of the constituent units of the present Federal Security Agency.

who testified confined their objections to the specific wording of the two Senate bills, S. 140 (Fulbright-Taft Bill) and S. 712 (Aiken Bill), and the only real opposition to this grouping of functions came from the members of the medical profession. Their opposition was related to having health grouped with education and security functions, in the fear that health interests would be subordinated to public welfare and social security. Organized medicine expressed itself in favor of a Department of Health or, failing that, an independent health agency. Other groups, such as consumer protection group, and proponents of child welfare, expressed fears that their interests might not be adequately represented in a new department. However, aside from that of members of the medical profession, no testimony at the hearing expressed real opposition to cabinet status for governmental functions in the fields of health, education and security.

Assistance Programs, Fiscal Year July 1, 1946 to June 30, 1947

Taxes Collected 1946-1947	Beneficiaries June 1947	Trust Fund, as of June 30, 1947	Method of Financing
General tax sources	2,271,007	None	Public assistance payments are made by state and/or local welfare agencies, from state and local funds, with the aid of federal grants. The programs are noncontributory; except in a few states, there are no taxes specifically earmarked for this purpose
General tax sources	1,000,475	None	
General tax sources	79,031	None	
General tax sources	335,000	None	General assistance payments are made by state and local welfare agencies, from state and local funds. There is no federal participation at the present time. The programs are noncontributory; except in a few states, there are no taxes specifically earmarked for this purpose
\$1,452,492,000	Primary only: 797,927 Total: 1,832,285 (Includes dependents and survivors)	\$8,728,015,000	No state participation. Financed by Federal Insurance Contributions Tax, at present 1 per cent of wages up to \$3,000 per year on both workers and employers in covered industries, or a total of 2 per cent of taxable payroll
\$380,057,000	Primary: 180,184 Total: 231,213 (Includes survivors)	\$821,858,000	Financed by federal payroll taxes on railroads and employees, on wages up to \$3,600 per year. Tax rate on each rose from 3.5 per cent to 5.75 per cent in January 1947, or a total of 11.5 per cent of taxable payroll
State: \$1,021,504,000 Federal: \$184,823,000	1,006,000 (weekly average)	\$7,869,011,000	Financed by payroll taxes on employers only on wages up to \$3,000 per year in covered industries. Federal tax is 0.3 per cent of taxable payroll; state taxes now average about 1.5 per cent. Administration costs are paid from federal grants to states; benefits are paid from state trust funds
\$141,750,000	24,000 (daily average)	\$859,408,000	Financed by federal payroll taxes on railroads of 3 per cent of wages up to \$3,600 per year. No experience rating provisions. This tax will also pay the costs of temporary disability compensation starting July 1, 1947. No state participation

The department is given the following functions: (a) to promote, foster and encourage the development throughout the nation of services, facilities and activities in the fields of health, education, public welfare and related fields; (b) to collect and analyze statistics and make studies, investigations and reports on conditions, problems and needs in those fields in the United States and in other countries, and to disseminate and make available information in those fields; (c) to make reports and recommendations with respect to the most effective policies and methods for the promotion of health, education, public welfare and related services, including recommendations with respect to legislation and matters of administrative policy; (d) to advise and cooperate with international organizations functioning in those fields, and (e) to administer such federal programs, including grants in aid, and such powers, functions and duties in those fields as are assigned to it or provided through this or subsequent legislative enactment.

OPPOSITION TO THE BILL

Little opposition to the idea of a cabinet Department of Health, Education and Security came out at the hearings on bills S. 140 and S. 172. Representatives of special interests

SIGNIFICANCE OF CABINET STATUS

It would appear that while adoption of this bill would actually mean little change at present in activities covered by the three divisions of the department (at operating levels it would probably be confined to a new letterhead on the stationery), potentially it may have great significance. In the immediate future the Secretary of Health, Education and Security would sit in at cabinet sessions and would have direct access to the President. Even now, without cabinet status, the administrator of the Federal Security Agency is in close contact with the President. Oscar Ross Ewing has recently been appointed to this post, and his views have not yet been made public. However, the previous administrator and the President have both repeatedly stated their proposals for furthering the functions and activities of the Federal Security Agency in a variety of ways: nationalizing unemployment compensation and raising benefit levels; liberalizing coverage and benefit provisions of old age and survivors insurance; increasing federal grants for public assistance; extending public health services, and creating a major new function—an extended, comprehensive plan for compulsory federal health insurance.

To date, Congress has been reluctant to adopt these proposals for greatly increasing federal responsibilities and expenditures along such lines largely because of the heavy taxes which would be necessary to pay for them. A cabinet secretary of health, education and security may be more successful, for he would tend to have greater prestige with Congress.

WOULD A CABINET DEPARTMENT BE MORE EFFICIENT?

A cabinet department might be more efficient if it provided for a real consolidation of constituent units, elimination of duplication and overlapping and cutting down personnel require-

WOULD A CABINET DEPARTMENT BE MORE RESPONSIBLE TO CONGRESS?

Here, again, it is doubtful whether cabinet status per se would count for much. Both administrators of independent agencies and cabinet secretaries must go to Congress for legislative authority and for appropriations, and both have generally asked for constantly increased appropriations and expanding functions. There is no reason to believe that the situation would not be the same with a cabinet Department of Health, Education and Security, but there is some reason to expect that a cabinet

TABLE 2.—*Present Organization and Appropriations of the Federal Security Agency*

1. Anticipated benefit payments from O. A. S. I. trust fund.

2. Includes anticipated benefits from state unemployment compensation trust funds of \$900,000,000; federal grants to states of \$55,512,000 for administration of unemployment compensation, and \$300,000 anticipated unemployment benefits to seamen.

3. Federal share only; does not include anticipated state expenditures for old age assistance, aid to blind and aid to dependent children.

4. While the Children's Bureau has important health functions, it is now part of the Social Security Administration and thus included here in the security group.

Source: Federal Security Agency, office of the administrator.

The "security" group of the constituent units of the Federal Security Agency, with about one third of the total personnel, will have control over more than 92 per cent of the total funds available in fiscal 1947-1948. The "health" group, with over half of the personnel, will account for about 5.3 per cent of total anticipated expenditures. "Education" trails a poor third, with less than one twenty-fifth of the personnel and less than 2 per cent of the funds. It would appear that there is some justification for the fear on the part of some persons that educational and health interests in a cabinet Department of Health, Education and Security may be subordinated to "security" interests.

ments. It appears that on the whole the administration of the Federal Security Agency has been effective and efficient. However, the constituent units have functions which are not closely related. As a result, coordination among them has tended to be loose, and the separate branches within the agency have operated much as if they were independent of each other. It is possible that a drive for effective coordination and economy could readily be made under the existing set-up. Cabinet status would not be necessary for this. A cabinet secretary may be more interested in efforts toward further expansion of the functions of his department.

secretary, enjoying greater prestige with the President and with Congress, may be more successful. Indeed, a cabinet secretary is primarily a political figure, whereas an independent career official may be first an administrator and only second a politician.

SHOULD A CABINET DEPARTMENT GO BEYOND MAKING RECOMMENDATIONS?

As clearly stated in the bill, one of the functions to be granted the new department is to make reports and recommendations on legislation and matters of administrative policy. Under a

similar provision of the original Social Security Act, the Social Security Administration has been in the past and is now active in recommending legislation. Recommendations have generally taken the form of proposals for broadening coverage, increasing benefits and raising taxes under present social security programs—and for including compulsory health insurance in social security. The Social Security Board, now the Social Security Administration, has liberally interpreted its function for recommending additional legislation. It is possible that its officials look forward to cabinet status in the hope that their proposals will receive more favorable attention.

SHOULD OTHER AGENCIES BE INCLUDED?

A section of S. 140 delegates to the Bureau of the Budget the task of studying functions now in other agencies and departments of the federal government with a view to possible inclusion in the proposed Department of Health, Education and Security ". . . in the interest of economy and simplicity of administration." Agencies which might thus be considered include the Bureau of Human Nutrition and Home Economics now in the Department of Agriculture, the Railroad Retirement Board, the Federal Public Housing Authority, the Office of Indian Affairs now in the Department of Interior, probation and parole work now in the Department of Justice, educational activities now in the Smithsonian Institution and the Veterans Administration. All these agencies function in fields more or less related to health, education or public welfare, and there may be others. The Bureau of the Budget is directed to submit its recommendations to Congress in a designated period of time. The effect of their inclusion (which, however, would probably be opposed by those who have special interests in these agencies) would be to expand further the functions, personnel and expenditures of the department.

PUBLIC ASSISTANCE AND THE FEDERAL GOVERNMENT

At the present time there is no federal participation in general assistance, or direct public relief, other than for the categorical aid programs (old age assistance, aid to the blind and aid to dependent children). Both total costs and the federal share for these programs have steadily increased, despite high prosperity and employment. There is a movement to obtain regular federal aid for general assistance as well as categorical programs, and it is general assistance which fluctuates most directly with the level of economic activity. If such proposals are adopted, they would greatly increase federal expenditures and administrative scope even under full employment.

IN THE EVENT OF A DEPRESSION

It is to be hoped that the nation will not again face an economic crisis such as that of the thirties, with widespread unemployment and acute distress. Nevertheless, the possibility must be faced. During that period, the federal administration obtained congressional approval for unprecedented welfare measures. A large group of powerful independent agencies were established for direct and work relief, including the Civil Works Administration, the Federal Emergency Relief Administration, the Public Works Administration, Civilian Conservation Corps, National Youth Administration and Works Progress Administration. These agencies accounted for a major share of federal expenditures in the thirties. While some of them continued in existence for several years after the economic emergency had subsided, nevertheless, as temporary agencies, they were eventually disbanded.

With a cabinet Department of Health, Education and Security, the logical place for the expansion of relief measures would be within that department. Functions that in the thirties were assigned to temporary agencies would probably go to the department; indeed, the department would likely have sufficient political strength to play a major part in initiating legislation to this effect. There is danger that a single cabinet department, combining extensive regular functions with a new F.E.R.A., W.P.A., N.Y.A. and C.C.C., might obtain such power and control over public funds as to constitute a real threat to democratic government and freedom of enterprise.

Then, too, incorporation of emergency functions in a permanent department may tend to have the effect of perpetuating such functions long after the reason for their establishment

TABLE 3.—Provisions of S. 140

Introduced by:	Fulbright, Democrat, Arkansas; Taft, Republican, Ohio
Date:	Jan. 10, 1917
Disposition:	Reported with amendment by Aiken, R., Vermont, by Committee on Expenditure in the Executive Departments, on June 6, 1917
Title:	"Health, Education, and Security Department Act of 1917": A bill to create an executive department of the government to be known as the Department of Health, Education and Security
Administrative heads:	Under direction of the Secretary of Health, Education and Security at \$15,000 a year (The secretary is to appoint advisory committees to consult on matters of policies and procedures) Under Secretary for Health at \$12,000 a year Under Secretary for Education at \$12,000 a year Under Secretary for Public Welfare at \$12,000 a year (One of these to act as secretary in case of absence or vacancy in the secretary's office)
Purpose of department:	"To promote the general welfare of the people of the United States by aiding and fostering progress . . . in the fields of health, education, public welfare and related services
Duties of department:	"1. Promote, foster and encourage the development . . . of services, facilities and activities in the fields of health, education, public welfare and related fields "2. Collect and analyze statistics and make studies, investigations and reports on conditions in those fields in the United States and other countries, and disseminate and make available information in those fields "3. Make reports and recommendations with respect to the most effective policies and methods for the promotion of health, education, public welfare and related services, including recommendations with respect to legislation and matters of administrative policy "4. Advise and cooperate with international organizations functioning in those fields "5. Administer such federal programs, including grants-in-aid, and such powers, functions and duties in those fields as are assigned to it or provided through this or subsequent legislative enactment"
Administrative system:	Creates the following bureaus, with designated transfers. Divisions of the department are to be, in order of descending ranking, bureaus, divisions, branches, sections and units Bureau of Health.—U. S. Public Health Service, Food and Drug Administration, Freedmen's Hospital and St. Elizabeths Hospital Bureau of Education.—U. S. Office of Education plus Howard University, American Printing House for the Blind and the Columbia Institution for Deaf Bureau of Public Welfare.—Social Security Administration Transfers existing personnel, equipment, appropriations, etc. of the foregoing agencies. In addition, the secretary is authorized to appoint a general counsel and to create such additional divisions, branches, etc., as he deems necessary
Grants-in-aid:	The secretary is directed to establish uniform standards and procedures relating to fiscal, personnel and other requirements for grants, and standards and procedures to enable state agencies receiving more than one grant to submit a single plan of operation and to be subject to a single fiscal and administrative review of its operation
Reports to Congress:	The secretary is required to prepare a report to Congress at the close of each fiscal year, giving an account of expenditures, describing the work done by the department, and making such recommendations as he deems necessary
Effective date:	Ninety days after date of enactment
Transfers of other agencies:	Director of the Bureau of the Budget is authorized and directed to study activities of other departments and agencies in the federal government and report to Congress on whether any of them should be transferred to the new department in the interest of economy and simplicity of administration

has disappeared. These possibilities may seem remote at present, but they merit careful consideration from both Congress and the public in weighing the cabinet proposal.

WHAT ABOUT THE FURTHER DEVELOPMENT OF FEDERAL AND STATE RELATIONSHIPS?

Of more immediate interest is the need for a clear definition of the division between federal, state and local responsibility for matters of health, education and public welfare. Expansion of social activities at all levels of government has been piec-

Chart 2.—Public expenditures for health and medical care services. Total public expenditures for health and medical care services increased 58.5 per cent from 1941 to 1945, while the federal share increased 167 per cent. Not included are health services incidental to other functions, such as public assistance, the Army, the Navy and education. Source: Social Security Yearbooks.

meal, in response to specific needs and demands. The line of demarcation between areas of responsibilities grows ever hazier. There are those who believe that these matters are and should be the responsibility only of states, individuals and communities. In contrast, others believe that local groups cannot be relied on to handle them and that the federal government alone should take over the task of providing health and social services. By way of compromise between these two extreme views, the grants-in-aid principle has been the means of extending federal participation (chart 4).

The effect of a cabinet department may be to hasten federal encroachment. The bill would not prevent such a development. Its only safeguard of local and voluntary interests is the

Chart 3.—Total costs for categorical aid programs of public assistance (old age assistance, aid to the blind and aid to dependent children). Total costs for these programs have risen 68 per cent in seven years, while the federal share has nearly doubled. Source: Social Security Administration. Includes benefits and administration. Column marked (1) excludes administrative costs paid from state sources; not yet available.

following sentence in the bill: “. . . Nothing in this Act shall be construed as conferring on any Federal officer or employee the right to exercise any supervision or control over the administration, personnel or operation of any State or local agencies, public or voluntary, in the fields of health, education,

public welfare or related services. . . .” This sentence, added by the Senate Committee on Expenditures in Executive Departments, replaced the original wording in the bill as introduced by Senators Fulbright and Taft:

“. . . The Department shall promote the general welfare of the people of the United States by aiding and fostering progress throughout the Nation in the fields of health, education, security, and related services contributing to individual, family and community well-being; and these objectives shall be carried out to the fullest possible extent through State and local agencies, public and voluntary, and in such manner as to preserve and protect to the highest possible degree the independence and autonomy of State and local agencies, public and voluntary, in education, health, security and related fields. . . .”

It is apparent that the amended version of the bill weakens the provision on behalf of local and voluntary interests in these fields. The bill does not require federal development or encouragement of local interests. If adopted in its present form, the effect of the bill (depending partly on federal administrative policy) may well make for discouragement of voluntary and local action.

Before action is taken on the cabinet proposal, it would appear that an essential first step would be discussion of the proper relationship between federal and state-local responsibility. This relationship should be clarified, and it is desirable

Chart 4.—Federal grants to states for health, education and security purposes by fiscal years ending June 30:

(1) Maternal and child health and welfare services, public health services, venereal disease and tuberculosis control, vocational rehabilitation, state and territorial homes for disabled soldiers and sailors, emergency maternity and infant care, and school-lunch program. 1947 data not yet available.

(2) Education of the blind, agriculture and mechanical arts colleges, marine schools, vocational education, training of war workers and services for farm labor, 1947 data not yet available.

(3) Old age assistance, aid to dependent children and aid to blind.

(4) Unemployment compensation administration; employment services through 1941.

Since 1943, there has been a decline in grants to states for education, due to the curtailment of defense training programs. Grants for employment security purposes have shown some fluctuation, but grants for public assistance and health and welfare services have steadily increased. In the last two years public assistance grants have risen more than 50 per cent, from \$421.2 millions in 1946 to \$644.1 millions in 1947. Source: Social Security Yearbook, 1945, and Social Security Bulletin, September 1947.

that such clarification should come at a period such as the present when there is no economic crisis bringing pressure on Congress for immediate federal expansion.

In conclusion, it is doubtful whether granting cabinet status to the Federal Security Agency has any real value other than a frankly political one. On the other hand, this proposal, of little apparent significance in the immediate future, may contain implications for the potential growth of the Department of Health, Education and Security of such magnitude as to merit careful consideration. Further study of all possibilities is necessary before Congress acts on S. 140.

Official Notes

RADIO PROGRAMS

The A.M.A.-N.B.C. radio program, "Doctors Today," which opened Dec. 13, 1947, is scheduled to run for twenty-six consecutive weeks at 3 p. m. each Saturday, Chicago time. The exact number of stations taking the program will be announced when available; the 1947 series "Doctors—Then and Now" was broadcast by approximately one hundred and forty stations coast to coast.

"Doctors Today" is a program based on timeliness and therefore subject to change. The following schedule is tentative. Announcement of changes will be made in THE JOURNAL whenever possible, but there may be times when the program broadcast will not coincide in subject or title with that previously announced.

Whenever possible programs canceled in favor of more timely ones will be broadcast later in the series.

Following is the schedule for programs now contemplated:

January 10, Care of the Chronically Ill.
January 17, Alcoholism.
January 24, Federal Control of Drugs
January 31, Urgent Need for Nurses.
February 7, Health in Rural Schools.

Washington Letter

(From a Special Correspondent)

Jan. 8, 1948.

Insanity Rate Higher in War Years

The U. S. Census Bureau reported that there was an increase in insanity among Americans during the war years, 1940 through 1945, especially among men in the military age bracket. The question was posed whether the "psychologic hazards of military life" drove more men insane or whether the intensive psychiatric scrutiny given men in this age group detected more cases of insanity. The increase in insanity among women paralleled that of men, but it was less in the 20 through 34 age group. The report covered the rise in the rate of first admissions of psychotic persons and it ignored hospital admissions of psychoneurotics and marginal disorders such as alcoholism, mental deficiency or drug addiction. The estimated number of first admissions to hospitals for permanent care of all patients with psychosis increased from 71.7 in each hundred thousand of population in 1940 to 86.8 in 1945, an increase of about 21 per cent. The number of men admitted to hospitals as psychotics was 78.8 per hundred thousand in 1940 as against 96.4 in 1945. Admissions more than doubled among men aged 20 to 24, rose 78 per cent among those aged 25 to 29 and rose 36 per cent among those aged 30 to 34.

Hawley Reports Veterans Administration May Lose Fourteen Hundred Doctors

Major Gen. Paul R. Hawley, former veterans' administrator, reported just prior to his retirement that the agency faces the loss of more than fourteen hundred physicians next spring, when terms of young officers trained in the wartime Army specialized training and V-12 programs expire. Many of the officers were assigned to isolated hospitals for which it was difficult to obtain civilian personnel, and many of them have expressed their intention to leave the agency on completion of the two year terms. The agency employs about sixty-seven hundred physicians in its hundred and twenty-six hospitals serving 118,000 patients.

Order to Curb Venereal Disease

Army Secretary Kenneth C. Royall has issued orders for a new drive to combat venereal disease among enlisted men. Officers and men who become infected are prohibited from leaving camp for thirty or even ninety days and are denied the right to visit their homes for at least thirty days after being cured; promo-

tions will be withheld for men with repeated infections; cooperation with civilian authorities in combating prostitution near military establishments and in sponsoring athletic and recreation programs will be encouraged.

Office of Scientific Research and Development Abolished

President Truman signed the executive order abolishing the wartime Office of Scientific Research and Development, the duties of which were absorbed by the unified armed services. Dr. Vannevar Bush, former head of the Office of Scientific Research and Development, is chairman of the new research and development board set up within the national military establishment under the unification act.

Federal Aid for Needy College Students Urged by Presidential Commission

The President's Commission on Higher Education advocates that \$135,000,000 be provided by the federal government to aid needy college students in 1948-1949. The expenditure was proposed as a starting point for federal assistance to equalize educational opportunity for deserving students throughout the nation.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Admission of Mental Patients at Saint Elizabeths Hospital

Companion bills have been introduced to provide for the voluntary admission and treatment of mental patients at Saint Elizabeths Hospital, S. 1810, introduced, by request, by Senator Taft, Ohio, and H. R. 4552, introduced by Representative Buck, New York. The Superintendent of the Hospital would be authorized, with the approval of the Federal Security Administrator, to prescribe such regulations as he shall deem necessary to carry out the provisions of the legislation.

National Board of Medical Examiners

A pending bill, H. R. 4636, introduced by Representative Miller, Nebraska, proposes to amend the healing arts practice act of the District of Columbia so as to authorize the issuance of licenses, without examination, to applicants who hold certificates issued by the National Board of Medical Examiners.

Importation of X-Ray Film

A bill introduced by Representative Andresen, Minnesota, proposes to amend paragraph 1629 of the Tariff Act of 1930 so as to provide for the free importation of exposed x-ray film. The purpose of this legislation is apparently to permit patients who have received treatment abroad to bring in to this country free of any tariff roentgenograms which may have been taken in connection with such treatment.

Hospital Construction

Delegate Bartlett, Alaska, proposes by H. R. 4816 to amend the federal hospital survey and construction act so as to provide the minimum allotment of \$250,000 to each state for the construction of hospitals.

A bill introduced by Representative Fallon, Maryland, provides that the funds heretofore appropriated for the construction of a Veterans' Administration tuberculosis hospital in Baltimore shall be used for the construction in that city of a general medical and surgical hospital.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 9-10. Dr. Donald G. Anderson, 535 North Dearborn St., Chicago 10, Secretary.

National Conference on Rural Health, Chicago, Palmer House, Feb. 6-7. Dr. F. S. Crockett, 535 N. Dearborn St., Chicago 10, Chairman.

American Academy of Orthopaedic Surgeons, Chicago, Palmer House, Jan. 24-29. Dr. Harold B. Boyd, 869 Madison Ave., Memphis, Tenn., Secretary.

American Society for Surgery of the Hand, Chicago, Jan. 23-24. Dr. Joseph H. Boyes, 1401 S. Hope St., Los Angeles 15, Secretary.

Southeastern Allergy Association, Richmond, Va., Jefferson Hotel, Jan. 17-18. Dr. Katharine B. MacInnis, 1515 Bull St., Columbia 49, S. C., Secretary.

GOVERNMENT SERVICES

ARMY

IMPROVEMENTS IN ADVANCED TRAINING FOR MEDICAL OFFICERS

The Surgeon General announced December 20 a number of changes in the Medical Department graduate education program for the coming year, based on nine months' operation of the program and surveys made by civilian medical experts. The innovations, effective immediately, are designed to maintain the quality of patient care and to elevate the caliber of training at Army general hospitals. The major changes are as follows:

Graduate training in psychiatry is being strengthened and concentrated in three general hospitals—Letterman (San Francisco), Fitzsimons (Denver) and Walter Reed (Washington, D. C.). This plan will afford each resident more individual instruction. Many qualified civilian consultants will be added to the attending staffs of the hospitals which are engaged in teaching. The administrative responsibilities of qualified teachers will be lessened by the transfer of routine paper work to administrative assistants assigned from the Medical Service Corps. Qualified instructor personnel will be kept on duty in their present assignments for as long as possible. When it becomes necessary to move them, they will be placed in locations where they will be able to teach.

Special instruction in the best methods of medical education is being provided for key military instructor personnel by means of short courses at selected civilian medical institutions. The number of conferences at which attendance by residents and interns is required is being reduced. Where possible, these will be held at times that will not interfere with bedside teaching. Likewise, the administrative duties of student officers are being reduced to the bare minimum consistent with excellent care of patients under their supervision. More adequate means of resident-intern selection and evaluation of progress are being placed in operation. Personal interviews will receive special emphasis. The present obstacles in the organization of interns and residents into the accepted pyramidal system are being overcome, so that the student officers may be given increased responsibility in care of patients, teaching and the supervision of others as they progress from one year of training to the next.

The Surgeon General pointed out that the improvements are a part of a continuing effort to place Army teaching hospitals on an equal plane with the best civilian teaching hospitals. He reported that the internists, surgeons and psychiatrists who surveyed nine Army general hospitals found that professional training compares favorably, for the most part, with the residency training given at civilian teaching centers with which they are familiar.

At present two hundred and four officers of the Regular Army Medical Corps are participating in the postgraduate instruction program as residents. The objective of each is certification as a diplomate by one of the specialty boards. In addition, fifty positions were made available on January 1 to applicants for the Regular Army who are now in the continental United States, and fifty more will be offered to applicants who are overseas effective July 1. The Surgeon General will furnish further information to interested doctors.

Of the one hundred and six applicants who have been approved thus far for internships beginning July 1, thirteen had a scholastic standing among the first ten of their class. Thirty others stood in the first third of the respective classes, and fifty-eight were in the middle third.

The hundreds of Army physicians who will receive internship and residency training this year and next, with some of the nation's leading specialists as well as war-seasoned military medical personnel as their instructors, constitute a group separate and distinct from others receiving special courses in civilian hospitals and schools.

GENERALS NOMINATED FOR PROMOTION

The Army's First Selection Board under the new Officer Personnel Act has submitted to President Truman the names of seventy-six officers for promotion to the grade of permanent major general and ninety-two for promotion to permanent brigadier general in the Regular Army. The President has approved the list and sent it to the Senate for confirmation. In the medical corps the following five were recommended for confirmation to major general: George C. Beach Jr., Raymond W. Bliss, Malcolm C. Grow, Albert W. Kenner and John M. Willis; the five recommended for permanent promotion to brigadier general are James A. Betha, Guy B. Denit, Joseph I. Martin, Edward A. Noyes and Omar H. Quade.

AFFILIATED UNITS OF THE MEDICAL DEPARTMENT

Eleven medical schools and hospitals to date have signed agreements with the Department of the Army to sponsor affiliated units of the Medical Department, thus becoming integral members of the organized Reserve. In making the announcement Major Gen. Raymond W. Bliss, the Surgeon General, expressed gratification with the response, adding that he confidently expects many more institutions to join in coming months.

Medical Schools of the Universities of Texas, Illinois, Wisconsin, Marquette, Ohio State, Duke and Baylor have completed negotiations to sponsor affiliated units, as have the following hospitals: Mount Sinai (New York), Cook County (Chicago), Rochester General (Rochester, N. Y.) and Boston City Hospital (Mass.).

The affiliated unit inaugurated by the Army in World War I proved to be an invaluable asset in World War II, when some five hundred affiliated units—not only medical but signal, railroad, engineering and numerous other types—saw service in all theaters of operations.

MEETING OF MEDICAL OFFICERS IN KOREA

At the regular monthly meeting of U. S. Army medical officers stationed in Korea at the 34th General Hospital, Dec. 17, 1947, among those present were Col. G. N. Schuhmann, M. C., U. S. A., and Col. R. E. Blount, M. C., U. S. A., who were visiting Korea as consultants in preventive medicine and medicine, respectively. The following papers were presented: "The Action of Anesthetics on Respiration" by Capt. Clara A. Vezina, A. N. C., discussed by Lieut. Kay Shaffer, A. N. C.; "Functional Illness" by Capt. Raymond C. Perkins, M. C., discussed by Colonel Blount and Capt. Irving Schulman, and "Preparation of Hospital Records" by Capt. Charles A. Cubbler, S. C. Dr. Philip Jaisohn, a Korean patriot who addressed the November meeting, spoke on "Adventures in Recent Korean History." Dr. Jaisohn is 81 years of age; he is now acting as special advisor to Lieut. Gen. John R. Hodge, commanding general, U. S. Army Forces in Korea. There were also ward rounds and departmental conferences. The hospital registrars in Korea were especially invited to attend this meeting. The chairman was Lieut. Col. John J. Marren, commandant of the 34th General Hospital. The business meeting was in charge of Col. Charles P. Ward, M. C., surgeon, 24th Corps.

PERSONAL

Dr. Henry M. Thomas, colonel, M. C., reserves, of Baltimore, has been placed on active duty for a period of five weeks, as medical adviser to Major Gen. Willard S. Paul, director of Personnel and Administration (G-1) Department of the Army.

NAVY

GROUP TO STUDY CHOLERA EPIDEMIC IN SYRIA

The Medical Department of the Navy is sending four specialists to Syria to study the cholera epidemic in Damascus and other parts of Syria. Emphasis will be placed on preventive and epidemic control measures. The party will consist of Lieuts. (jg) Richard H. Weaver (MC), U. S. N. R., of Kalamazoo, Mich., and Moulton K. Johnson (MC), U. S. N. R., of Washington, D. C.; Chief Pharmacist Mate James D. Gillmore, U. S. N., of Mount Vernon, Wash., and Pharmacist Mate, first class, Charles F. Robinson, U. S. N., of Corpus Christi, Texas. The group is now on duty at Naval Medical Research Unit 3 in Cairo, Egypt. Each member of the Syrian party is an expert in the prevention and control of cholera, and each participated in the recent naval medical program which assisted the Egyptian government to curb the cholera epidemic in Egypt.

MEETING OF HONORARY CONSULTANTS

The Honorary Civilian Consultants to the Medical Department of the Navy met December 5 in Washington, D. C. The consultants, who are appointed by the Secretary of the Navy, act as an advisory board to assist in formulating policies for the Bureau of Medicine and Surgery. The welcoming address was made by the Under Secretary of the Navy, the Honorable W. John Kenney. The Surgeon General, Rear Admiral Clifford A. Swanson (MC), opened the meeting with a discussion of the problems facing the Medical Department for the coming year and was followed by Rear Admiral H. Lamont Pugh (MC), Deputy Surgeon General, who spoke on the Bureau's organization. The consultants were: Dr. Edward L. Bortz, President, American Medical Association, Philadelphia; Dr. Roscoe L. Sensenich, President-Elect, American Medical Association, South Bend, Ind.; Dr. Joseph L. Appleton, Philadelphia; Dr. Richard R. Cattell, Boston; Dr. Robert P. Fischelis, Washington, D. C.; Dr. Evarts A. Graham, St. Louis; Dr. Frank H. Lahey, Boston; Dr. Oswald S. Lowsley, New York; Rev. Paul McNally, Washington, D. C.; Dr. Clyde E. Minges, Rocky Mountain, N. C.;

Dr. James Edgar Paullin, Atlanta, Ga.; Dr. Charles Sheard, Rochester, Minn.; Dr. W. Calhoun Stirling, Washington, D. C.; Dr. Edward A. Strecker, Philadelphia, and Dr. Meyer Wiener, Coronado, Calif.

APPOINTMENT OF COMMISSIONED OFFICERS IN THE REGULAR NAVY

The Army-Navy-Public Health Service Medical Officer Procurement Act of 1947 makes it possible now for civilian doctors to become commissioned officers in the regular Navy, provided they meet the professional and physical qualifications. This law is unique in that it does away, for the first time, with the age limitation of 32 years and permits doctors in civilian practice to enter the Navy and be commissioned with the rank up to and including captain. The law considers all strata of the medical profession, interns, residents, reserves, former medical officers who have resigned and presently practicing physicians.

To make application a physician must be a citizen of the United States, a graduate from a class A medical school and must have served at least one year's internship in an approved hospital. Candidates will then be judged on a number of qualifications such as being a member of a specialty board, teaching connections, the number of years of professional or scientific practice, hospital or laboratory connections and a statement of military service.

The allocation of rank to successful candidates will depend on their academic age, professional standing and experience in the medical field. Successful candidates will then be integrated in line with medical officers of the regular Navy and assigned running mates accordingly. This means that they will be eligible for promotion along with their fellow officers of equal rank.

This law offers an opportunity for civilian doctors to make a career in the regular Navy and to enjoy its professional advantages as well as its retirement benefits. Doctors interested in such a career should write to the Bureau of Naval Personnel, via the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

PUBLIC HEALTH SERVICE

GRANTS FOR TRAINING AND RESEARCH IN PSYCHIATRY AND PSYCHOLOGY

Applications for training and research grants in psychiatry, clinical psychology, psychiatric social work and psychiatric nursing in connection with the program of the U. S. Public Health Service authorized under the Mental Health Act for the fiscal year beginning July 1, 1948 should be received not later than January 15. Final action will be taken on these applications at the next meeting of the National Advisory Mental Health Council in Washington, D. C., May 14-15. Applications for training grants should be sent to the Training and Standards Section and applications for research grants to Research Projects Director, Mental Hygiene Division, U. S. Public Health Service, Washington, D. C.

GRADUATE INSTITUTE IN KENTUCKY ON PSYCHOSOMATIC MEDICINE

The Mental Hygiene Division of the U. S. Public Health Service, in cooperation with the Kentucky State Medical Association, Kentucky Psychiatric Association and Kentucky Department of Health, is holding a postgraduate institute in psychosomatic medicine and mental hygiene at Lexington, Ky., February 3 to 6. Physicians in Kentucky and adjoining states are invited. There is no registration fee. The speakers will include authorities from various states. Among the presentations will be a symposium on drug addiction and another on infant and child behavior, papers on diagnosis and care of epilepsy, psychologic aspects of rheumatoid arthritis, psychic factors in cardiovascular diseases, and the court psychiatrist's view of

crimes. On Friday at a joint meeting with the Kentucky Psychiatric Association there will be papers on early schizophrenia and schizoid personality, and psychotherapy for practitioners.

The U. S. Public Health Service is using funds from the appropriation provided by the mental health program for the institute, and if it is well received by physicians similar institutes will be held elsewhere. Those desiring to attend should write direct to the hotels for reservations, mentioning the institute. Blocks of rooms have been reserved in the Lafayette and Phoenix hotels; other hotels in Lexington are the Drake and the Kentuckian.

RECLASSIFY OCCUPATIONAL THERAPISTS

Professional standards for all occupational therapists in the U. S. Public Health Service have been authorized, according to federal security administrator Oscar F. Ewing. Occupational therapists in hospitals operated by the service will be reclassified from subprofessional to professional grades P1, P2 or P3, if they are graduates of approved schools of occupational therapy, or have experience giving them comparable qualifications, and are performing professional occupational therapy.

Unlike the physical therapist category, which also was recently converted to professional status, the subprofessional status for occupational therapists will not be eliminated. Occupational therapy aides still will be needed in the subprofessional grades. Qualified occupational therapists of the U. S. Public Health Service will not be converted from subprofessional to professional status immediately. Individual job descriptions must first be prepared by the incumbents and reviewed by the Classification Section in order to determine the appropriate professional grade.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Dr. Houssay Delivers Hitchcock Lectures.—Dr. Bernardo A. Houssay of Buenos Aires delivered the Hitchcock Lectures at the University of California, Berkeley, beginning January 8. The lectures, presented periodically under the Hitchcock Foundation, are open to the public. In his lectures Dr. Houssay, who is director of the Institute of Biology and Experimental Medicine in Buenos Aires, partially covered the work for which he, as co-winner, was awarded the Nobel Prize in Medicine in 1947.

Disease Prevention Week in Los Angeles.—The fourth observance of Disease Prevention Week is set for February 15-22 in Los Angeles. The Community Health Association of Los Angeles will conduct the activity in cooperation with the city and county health departments, the county medical association and its Women's Auxiliary, and numerous social and welfare agencies. The public will be invited to sessions that will run all day Wednesday, February 18, in the Biltmore Hotel, Los Angeles. Health exhibits will be displayed in the morning, a luncheon with distinguished speakers will be given at noon, and papers by health authorities will be delivered during the remainder of the day.

Society News.—Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, will address the regular monthly meeting of the Alameda County Medical Association January 15 in the Scottish Rite Temple in Oakland at 8:15 p.m. on "The Present Status of Medical Legislation." The meeting is open to the members of the Bay area medical associations. Dr. Fishbein will also address the Oakland Rotary Club at its noontime meeting January 15 on "Innovations and Scientific Progress in Medicine."—The Los Angeles Society of Allergy, a section of the Los Angeles County Medical Association, has elected the following officers for 1948: Drs. Willard S. Small, Pasadena, president, and Frank G. Crandall Jr., Los Angeles, secretary-treasurer.—The Trudeau Society of Los Angeles at its meeting December 23 elected Dr. Joseph L. Robinson president and Dr. Arthur E. T. Rogers, secretary-treasurer.—The Los Angeles County Medical Association on Dec. 4, 1947 elected Dr. William H. Leake president, and Dr. Richard O. Bullis, secretary-treasurer. They took office January 1.

Dr. Stanley to Head Laboratory for Virus Research.—Wendell M. Stanley, Ph.D., of the Rockefeller Institute for Medical Research, Princeton, N. J., has been appointed to establish and direct a new laboratory of virus research at the University of California, Berkeley-San Francisco. Dr. Stanley will come to Berkeley in July. He will not only direct biochemical research on the Berkeley campus and at the medical school in San Francisco but also cooperate closely with the state program of the College of Agriculture in the same field. Dr. Stanley received his Ph.D. degree from the University of Illinois in 1927. He was a National Research Fellow in Munich, Germany, 1930-1931, and has been with the Rockefeller Institute for Medical Research since 1931 and a member since 1940. He was the Hitchcock professor at the University of California in 1941. In 1946 Dr. Stanley and John H. Northrop, Ph.D., were awarded one half of the Nobel Prize in Chemistry for their research on virus proteins (THE JOURNAL, Jan. 18, 1947, p. 191). Dr. Stanley also received the American Association for the Advancement of Science Prize in 1936, the Isaac Adler Prize by the Medical School of Harvard in 1938 and the Rosenberger Medal by the University of Chicago in 1938.

GEORGIA

Postgraduate Assembly in Atlanta.—The Fulton County Medical Society is sponsoring the Atlanta Postgraduate Medical Assembly at the Academy of Medicine, Atlanta, January 28-30. The speakers will be Drs. Lester Dragstedt, Chicago; Chester S. Keefe, Boston; Andrew C. Ivy, Chicago; Helen B. Taussig, Baltimore; Julius Lempert, New York; Philip S. Hench, Rochester, Minn.; Emmerich von Haam, Columbus, Ohio; Ralph M. Towell, Hartford, Conn.; Robert Elman, St. Louis; Tom D. Spies, Birmingham, Ala.; Merrill C. Sosman, Boston; Rufus F. Payne, Rome, and Robert B. Greenblatt, Augusta.

ILLINOIS

Personal.—Dr. Harry D. Nesmith of Salem has been appointed as surgeon for the Baltimore and Ohio Railway, a position for which he resigned after holding the position about thirty years. A. Cunningham,

Dr. Cheney Retires from Armour and Company.—After thirty-two years' service Dr. Volney S. Cheney, Chicago, retired Oct. 4, 1947 as medical director for Armour and Company and has been succeeded by Dr. Joseph A. Hubata, Chicago. Dr. Cheney, a graduate of Northwestern University Medical School, 1902, was surgeon for the company from 1916 to 1920, when he became medical director. He has retired and moved to Las Vegas, N. Mex. Dr. Hubata before his appointment served for nine years on the medical staff of the West Pullman Works of the International Harvester Company. He is a graduate of the University of Illinois School of Medicine, 1933.

County Society Honors Veteran Member.—Dr. John M. Palmer, Waukegan, was guest of honor at a recent testimonial dinner in Waukegan, sponsored by the Lake County Medical Society. The occasion marked the retirement of Dr. Palmer, who has spent his entire medical career of forty-six years in Lake County. Among the speakers was Dr. John B. Youmans, dean of the University of Illinois Medical School, Chicago, from which Dr. Palmer graduated in 1901. Dr. Palmer served in the Army medical corps in World War I and located in Waukegan when he returned to civilian life. He is a staff member of Victory Memorial and St. Therese hospitals in Waukegan.

Chicago

The First Holmes Lecture.—At a joint meeting of the Institute of Medicine, the Chicago Ophthalmological Society and the Society of Medical History of Chicago at the Palmer House, January 30, Dr. Edward V. L. Brown, Rush clinical professor emeritus of ophthalmology, University of Illinois College of Medicine, will deliver the first lecture under the Rudolph Wieser Holmes and Maria Baxter Holmes Fund. His subject will be "Edward L. Holmes: Pioneer Chicago Eye Doctor."

The Chicago Industrial Health Plan.—An educational program to raise the standards of industrial health and medicine among 1,500,000 workers in Cook County was launched January 1. The Chicago Industrial Health Plan is supported by community groups, health agencies, major labor unions, management groups and welfare associations. Mr. Lester M. Selif, president of the General American Transportation Company, is general chairman; Dr. Frederick W. Slobe, chairman of the Chicago Medical Society's committee on industrial medicine, is chairman of the executive committee, and Alexander Ropchan, executive secretary, health division, Council of Social Agencies, is secretary. Labor organizations are to name a co-chairman. A full time executive director, Percy Shostac, New York, who directed a similar program for Brooklyn, has been appointed. The plan is financed by the state, the Red Cross, the Tuberculosis Institute and the American Cancer Society. It is said that the program will endeavor to carry out recommendations made by the U. S. Public Health Service in its Chicago-Cook County Health Survey. It is hoped that industries will contribute to the educational program.

INDIANA

Hygeia Sent to Legislators.—The House of Delegates of the Indiana State Medical Association has presented members of the Indiana General Assembly with a year's subscription to *Hygeia*, the *Health Magazine*, published by the American Medical Association.

State Society to Award Keys.—The council of the Indiana State Medical Association has voted to present gold keys to the three seniors of the 1948 graduating class of the Indiana University School of Medicine, Bloomington-Indianapolis, who make the highest grades. The scholarship awards will be presented at commencement exercises next June.

Congressman Harness to Address Secretaries' Conference.—Congressman Forest A. Harness of Kokomo, representing the Fifth Indiana District, will be principal speaker at the annual Secretaries' Conference of the state medical association in Indianapolis on February 15. Head of a house committee investigating lobbying activities of federal employees, he will reveal strategy of the employees who are trying to influence Congress to pass legislation for socialized medicine. Other speakers will be Dr. Elmer L. Henderson of Louisville, Ky., chairman of the American Medical Association Board of Trustees, and Dr. Richard L. Meiling of Columbus, Ohio, secretary of the American Medical Association Council on National Emergency Medical Service. Dr. Albert M. Mitchell, Terre Haute, chairman of the conference committee, will preside.

LOUISIANA

Society News.—The Rapides Parish Medical Society will celebrate founders' day January 10 at the Bentley Hotel, Alexandria, with scientific papers beginning at 10 a. m., luncheon at 12:15 p. m. and an afternoon session ending at 4:30. Specialists and teachers on the staffs of Louisiana State University and Tulane medical faculties will address the group. In the evening following the annual banquet there will be an address by a guest speaker.

Matas Lectureship Established.—The Beta Iota Chapter (Tulane) of Nu Sigma Nu Medical Fraternity is inaugurating an annual lectureship in honor of its most famous member, Dr. Rudolph Matas, professor emeritus of surgery at Tulane University of Louisiana School of Medicine, New Orleans. The first lecture will be held on January 28 at 8 p.m. in the Hutchinson Memorial Auditorium of the Tulane Medical School. Dr. Alfred Blalock, professor of surgery at Johns Hopkins Medical School, Baltimore, the inaugural speaker, will lecture on "Surgical Treatment of Congenital Cardiovascular Defects." All members of the medical profession are cordially invited.

MICHIGAN

Hospital Staff Honors Dr. Wilson.—The medical and surgical staff of St. Mary's Hospital, Detroit, gave a testimonial dinner Dec. 3, 1947, for Dr. Walter J. Wilson at the Detroit Athletic Club in honor of his fifty years of practice. He was presented a plaque recording the history of his career. Dr. Wilson, a graduate of the Detroit College of Medicine, 1897, is a past president of the hospital's medical staff and a member of its executive staff.

NEW YORK

Nassau County Postgraduate Instruction.—Postgraduate instruction arranged by the Medical Society of the State of New York in cooperation with the New York State Department of Health for the Nassau County Medical Society will be given Tuesday afternoons at 4 o'clock in the Nassau Hospital auditorium, Mineola, as follows:

January 20, Dr. Lewis D. Stevenson, New York, Clinical Aspects of Encephalitis and Poliomyelitis.

January 27, Dr. Harry Most, New York, Tropical Disease, Civilian Implications of Military Experience.

February 3, Dr. Edward F. Hartung, New York, Diagnosis and Treatment of Low Back Pain from the General Practitioner's Point of View.

February 10, Dr. E. Charles Kunkle, New York, Headache Mechanisms.

Training Center in the Field of Atomic Energy.—According to the *Army and Navy Journal*, the U. S. Atomic Energy Commission has approved an expenditure of \$615,000 to build and equip a six story training and research center on the campus of the University of Rochester. This project was recommended by the commission's Advisory Committee on Biology and Medicine to provide facilities for training medical personnel to meet problems in the field of atomic energy. Under the program physicians will receive graduate training in the use of radioactive isotopes for tracer studies and therapy and in the treatment of radiation sickness; they will be instructed in the pharmacology and toxicology of radioactive materials, the design of radioactive chemical laboratories, principles of shielding, methods of decontamination and the disposal of radioactive waste materials.

New York City

Lectures for Laymen.—The New York Academy, continuing its series of Lectures to the Laity, will present the following program in 1948 at the Academy at 8:30 p.m.:

January 22, Dr. Edward J. Stieglitz, Washington, D. C., On Being Old Too Young.

February 4, Dr. Cornelius P. Rhoads, New York, Perspectives in Cancer Research.

February 26, Dr. William C. Menninger, Topeka, Kan., Psychiatry for Everyday Needs, the George R. Siedenburg Memorial Lecture.

March 11, James B. Conant, Ph.D., president, Harvard University, Cambridge, Mass., The Interrelation of Pure and Applied Science in the Field of Medicine.

Friday Afternoon Lectures.—The January and February program of the New York Academy of Medicine's Friday Afternoon Lectures, given at the Academy at 4:30 and open to members of the medical profession and medical students, is as follows:

January 16, Dr. Richard H. Freyberg, Diagnosis and Treatment of Arthritis.

January 23, Dr. Murray H. Bass, Recent Advances in Knowledge of Contagious Diseases of Childhood.

January 30, Dr. Paul Reznikoff, Diagnosis and Treatment of Anemia.

February 6, Dr. Thomas A. C. Rennie, Use and Abuse of Psychotherapy.

February 13, Dr. George M. Lewis, What's New in Dermatology?

February 27, Dr. Carl A. L. Binger, Management of the Emotional Side of Heart Disease.

Experiment in Cardiac Rehabilitation.—The Altro Work Shops, Inc., established thirty-two years ago under the direction of Mr. Edward Hochhauser and his associate Miss Celia Hentell for the rehabilitation of the tuberculous, has undertaken a two year experiment in the field of cardiac rehabilitation of the tuberculous. The facilities of Altro have been offered only to the quiescent or arrested tuberculous patient, for whom it helps to bridge the gap between hospital care and complete social integration. Case histories, including medical, industrial and social work data, together with other factors in the program will be evaluated at the end of the two year experimental period to determine the future content of the program. Minimum admission requirements have been set up. For the initial stage of the program only 20 patients will be admitted to facilitate the study of their progress. Inquiries and applications should be addressed, with the medical abstracts, to Altro Work Shops, Inc., 71 West Forty-Seventh Street, New York.

OHIO

University Establishes Eye Laboratory.—The ophthalmology department of the University of Cincinnati College of Medicine is establishing an eye laboratory under the direction of Dr. Donald J. Lyle, professor and head of the department. The work of the laboratory currently is concerned with the examination of eyes for diagnosis and the preparation of specimens for collection and study. Facilities and services of the laboratory will be available to physicians in Ohio, Indiana and Kentucky. The laboratory has taken over temporary quarters in Pavilion A of the Cincinnati General Hospital and is awaiting assignment to permanent quarters there. The first gift to support the laboratory has been made by the Eastern Hills Lions Club.

PENNSYLVANIA

Typhoid Following Wedding Reception.—Fifteen persons among seventy-six who attended a wedding reception near Lititz in Lancaster County on Thanksgiving Day became ill with typhoid, according to the Associated Press. All doctors in the county have been notified of the outbreak.

Seibert Memorial Award.—Dr. Charles W. Smith, Harrisburg, received the Seibert Memorial Award, having been an adjudged member of the Harrisburg Academy of Medicine under 45 years of age, who has done the most to advance medicine in the last two years. Dr. Smith, a former editor of the *Academician*, official publication of the Academy, is chairman of the committee on graduate education of the Medical Society of the State of Pennsylvania, which this year is conducting a graduate education institute in six centers throughout the state. Presentation of \$500 for postgraduate medical study, made possible by a trust fund created in memory of Dr. William H. Seibert, was made at a dinner meeting in the Penn-Harris Hotel, Harrisburg, at the close of the academy's sixteenth annual postgraduate assembly.

Pittsburgh

Huggins Memorial Lecture.—The second annual R. R. Huggins Memorial Lecture of the University of Pittsburgh School of Medicine will be given at 8:30 Friday evening, January 16, at the Mellon Institute Auditorium. The guest lecturer will be Dr. Joseph G. Hamilton of the University of California's Radiation Laboratory, speaking on "Application of Radioactive Substances to Clinical Medicine." The lecture is sponsored by the Phi Delta Epsilon Fraternity, Nu Chapter, and all interested are invited to attend.

TEXAS

Memorial Physiology Professorship.—Through contributions to Baylor University College of Medicine Alumni-Faculty Foundation and by faculty members and other friends, an endowment is being established for a professorship of physiology as a memorial to Dr. Benjamin F. Hambleton, a member of the faculty for twenty-seven years. The professorship will become effective at the beginning of the academic year 1948-1949. Dr. Hambleton was graduated from Ohio Wesleyan University Medical Department, Cleveland, and joined the department of physiology, where he served from 1901 to 1910. He was professor of physiology and pharmacology at Vanderbilt University from 1910 to 1919 and came to Baylor University College of Medicine, Dallas, in 1920 as professor of pharmacology and biochemistry. In 1930 he was appointed professor of physiology and pharmacology, continuing active until his sudden death Dec. 9, 1947, at the age of 75.

GENERAL

Meeting of Spanish Speaking Physicians.—The International Spanish Speaking Association of Physicians, Dentists and Pharmacists, Inc., will meet at the Waldorf-Astoria Hotel, New York, January 23, under the presidency of Dr. Jacob M. Gershberg, New York. Included on the program is a symposium on blood from the points of view of geriatrics, race, life, diseases and crime.

Southeastern Allergy Association.—The third annual meeting of the Southeastern Allergy Association will be held January 17-18 at the Jefferson Hotel, Richmond, Va., under the presidency of Dr. J. Warrick Thomas of Richmond. The program for Saturday includes panel discussions of nose and throat allergies, atopic dermatitis, the effectiveness of influenzal and rickettsial vaccines, and sudden death during skin testing. Guest speakers will be Dr. Karl D. Figley, Detroit, president, American Academy of Allergy, on "Some Unanswered Questions in Clinical Allergy" and Dr. Hal M. Davison, Atlanta, Ga., president, American College of Allergists, on "Allergy and Nutrition." Sunday's program includes a panel discussion and papers on periarthritis nodosa, sensitivity to alcoholic beverages and ascaris asthma.

National Conference on Medical Service.—A National Conference on Medical Service will be held at the Palmer House, Chicago, February 8 beginning at 9 a.m. under the presidency of Dr. Creighton Barker, New Haven, Conn. Subjects under discussion include two points of view on "The Practice of Medicine in Hospitals, Health Departments and Medical Schools," "Medical Public Relations Begin in the Doctor's Office," and "The Nursing Problem in America" in its educational, service and economic aspects. The luncheon speaker will be Robert Hutchins, chancellor, University of Chicago, speaking on "Are Medical Educational Requirements Too High—Should We Have More Doctors?" On the afternoon program are two panel discussions, one on General Practice and another on Specialty Boards.

Gastroenterologic Contest and Award.—The National Gastroenterological Association announces its Annual Cash Prize Awards Contest for 1948 for the best unpublished contribution to gastroenterology. Contestants residing in the United States must be members of the American Medical Association, and those in foreign countries must be members of a similar organization in their own country. The winner will be selected by a board of impartial judges, and the award of \$100 and a Certificate of Merit will be made at the annual banquet of the National Gastroenterological Association in June, 1948. The association reserves the exclusive rights to publish the winning contribution and those receiving certificates of merit in its official publication. Entries should be limited to 5,000 words, typewritten in English and submitted in five copies. They must be received not later than April 1, 1948 by the National Gastroenterological Association, 1819 Broadway, New York 23.

Research Fellowships in Medicine.—The American College of Physicians has awarded six Research Fellowships in Medicine for the year beginning July 1948 with stipends ranging from \$2,200 to \$3,200. Recipients and their fields of research are: Drs. Charles G. Campbell, Montreal, Canada, for studies of the basic physiology of certain cardiovascular problems, at McGill University Faculty of Medicine, Montreal; Frank H. Gardner, Boston, the mechanism and clinical application of the osmotic fragility test, at Thorndike Memorial Laboratory; Samuel P. Martin, Durham, N. C., bacterial metabolism, in the Rockefeller Institute for Medical Research, New York; Peritz Scheinberg, Miami, Fla., cerebral circulation and peripheral vascular flow in normal and hypertensive persons, in Duke Hospital, Durham, N. C.; Lutfu L. Uzman, Istanbul, Turkey, isolation and characterization of brain proteins and their role in health, disease and senescence, at McLean Hospital, Waverley, Mass.; John M. Weller, Hines, Ill., ionic patterns of the intracellular fluids and their influence on enzymatic reactions, at Harvard Medical School, Boston.

National Research Council Grants in Endocrinology.—The Committee on Research in Endocrinology, National Research Council, announces that requests for grants-in-aid during the fiscal year July 1, 1948 to June 30, 1949 will be received until Feb. 29, 1948. Application blanks may be obtained by addressing the Secretary, Division of Medical Sciences, National Research Council, 2101 Constitution Avenue, Washington 25, D. C. In addition to a statement of the problem and research program, the committee desires information regarding the proposed method of attack, the institutional support of the investigation and the uses to be made of the sum requested. No part of any grant may be used by the recipient for administrative expenses. The committee makes grants in aid of research in the

general field of experimental and clinical endocrinology. However, applications for support of research in the problems of sex in the narrower sense cannot be given favorable consideration, and investigators who seek support in this field should direct their proposals to the Committee for Research in Problems of Sex, National Research Council.

Annual Meeting of Orthopaedic Surgeons.—The American Academy of Orthopaedic Surgeons will hold its fifteenth annual meeting January 24-29 at the Palmer House, Chicago, under the presidency of Dr. Rexford L. Diveley, Kansas City, Mo. Among others, four distinguished foreign guests will speak: Dr. H. Osmond-Clarke, London, England, "Fractures of the Carpal Scaphoid"; Dr. Sten Friberg, Stockholm, Sweden, "The Problem of the Lumbar Intervertebral Disk—Some Pathologic and Clinical Aspects"; Professor Jacques Leveuf, Paris, France, "Treatment of the 'True' Congenital Luxation of the Hip. Results of the 'Open Reduction'," and Dr. Robert M. D'Aubigne, Paris, "Surgical Treatment of Nonunion of Long Bones." Numerous members of the academy and their guests will present thirty papers. On the Tuesday morning program is a symposium on Orthopedic Rehabilitation. A series of thirty-five instructional courses will be given beginning Sunday at 2 p.m. Seminars and cadaver demonstrations in anatomy have been added this year. The Audiovisual Program opens at 2 p.m. Saturday. There will also be scientific and technical exhibits. The annual dinner and dance will be Wednesday evening at 7:30.

FOREIGN

Postgraduate Summer School.—A Postgraduate Summer School will be held at the Medical School of the University of Birmingham, Birmingham, England, from July 10 to August 7, presenting courses on the physiology of sex hormones, fat absorption in experimental animals and man, and lipoprotein association in biologic systems. The school is intended for graduates who have done advanced work in the appropriate fields of science and medicine; it is open to men and women. The fee is £44 for board, residence and tuition. Applications from American students should be sent to the Director, Institute of International Education, 2 West 45th Street, New York 19, by March 15, 1948. The envelope should be marked "Birmingham University Medical Summer School."

Traveling Fellows from India.—Dr. Natesaier Purshotan, a pediatrician, and his wife Tara Deodhar Purshotan, a biochemist, of India are traveling throughout the United States on six months' fellowships from the United Nations, to observe particularly our methods of organizing public nutrition programs. Dr. Purshotan's ambition is to organize school lunchrooms based on American models throughout India, as only two cities in his country have school lunch programs at present. The new Indian government has established a Ministry of Health, and one of its first objectives will be better health for children, most of whom now are undernourished. The Purshotans recently visited the U. S. Public Health Service headquarters in Washington, D. C., where they were particularly interested in the nutrition surveys which that agency is conducting in communities in four areas of the United States and which are designed for the dual purpose of collecting data on the prevalence of deficiency disease and demonstrating methods for using the recent developments in the science of nutrition to prevent illness.

Marriages

HENRY CARL MESSERSCHMIDT JR., Richmond, Va., to Miss Betty Rowland Fidler of Burlington, N. C., Nov. 15, 1947.

JAMES WARREN VIDEMAN JR., Manning, S. C., to Miss Lillian Heyward Evans of Raleigh, N. C., Oct. 25, 1947.

JOHN J. HANLON JR., Harrisburg, Pa., to Miss Doris Marie Patrick of New Cumberland, Nov. 8, 1947.

FREDERIC PRATT HERTER, Boston, to Miss Harriet Ames Conel of Newton, Mass., Nov. 22, 1947.

JOSEPH L. STECHER, Baltimore, to Miss Hazel Heinmiller of Orlando, Fla., Oct. 18, 1947.

MILTON HAMLIN BLAND to Miss Joyce Elaine Gagner, both of Norfolk, Va., Oct. 25, 1947.

CHESTER CASSEL, Miami, Fla., to Miss Carol Isaacson of New York, Dec. 19, 1947.

EMANUEL CHUSID to Miss Alta Butkus, both of Chicago, Dec. 13, 1947.

Deaths

Frederic Ewald Sondern * New York; born in Stuttgart, Germany, March 30, 1867; College of Physicians and Surgeons, medical department of Columbia College, New York, 1889; an Affiliate Fellow of the American Medical Association, serving as a member of the House of Delegates from 1916 to 1921 and from 1932 to 1942; past president and formerly treasurer of the Medical Society of the State of New York; past president of the Medical Society of the County of New York; emeritus professor of clinical pathology and past president at the New York Post-Graduate Medical School and Hospital, Columbia University; served on the staffs of the Roosevelt, Bellevue and New York Lying-In hospitals; died in the New York Post-Graduate Medical School and Hospital Oct. 10, 1947, aged 80.

Christopher Adam Henry Arnecke * Arneckeville, Texas; University of the South Medical Department, Sewanee, Tenn., 1895; died Sept. 2, 1947, aged 87, of coronary occlusion.

Theodorus Bailey, New York; Columbia University College of Physicians and Surgeons, New York, 1899; at one time instructor at the New York Polyclinic; served on the staff of Manhattan State Hospital; died in Dania, Fla., Sept. 25, 1947, aged 72, of coronary occlusion.

William Augustus Ball * Wanette, Okla.; Chattanooga (Tenn.) Medical College, 1897; died recently, aged 74, of hypertension.

Daniel Bradley Brinsmade * Major, U. S. Army, retired, Belmont, Mass.; Columbia University College of Physicians and Surgeons, New York, 1900; entered the medical corps of the U. S. Army in 1920; retired Nov. 30, 1933 for disability in line of duty; served in France during World War I; at one time surgeon in charge of the Watertown (Mass.) Arsenal; died Sept. 25, 1947, aged 73, of cerebral hemorrhage.

William Henry Burgess * Orlando, Fla.; Louisville (Ky.) Medical College, 1907; at one time practiced in Williamson, W. Va.; member of the West Virginia State Medical Association; died Oct. 7, 1947, aged 80, of heart disease.

William James Burgess, Verona, N. J.; Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1901; affiliated with the Essex Mountain Sanatorium; died in St. Francis Hospital, Burlington, Iowa, Oct. 1, 1947, aged 69, of carcinoma of the bladder.

Charles Elbert Byler, Lepanto, Ark.; University of Tennessee College of Medicine, Memphis, 1914; died Sept. 23, 1947, aged 60, of coronary occlusion.

Edgar M. Carman, Vashti, Texas (licensed in Texas under the Act of 1907); member of the American Medical Association; died in Gladstone, N. Mex., recently, aged 75, of angina pectoris.

Albert C. Chenoweth, Huntington, Ind.; Hahnemann Medical College and Hospital, Chicago, 1908; died Oct. 6, 1947, aged 70, of cerebral hemorrhage.

Alvin Harvey Chilson, Plymouth, Iowa; State University of Iowa College of Medicine, Iowa City, 1913; member of the American Medical Association; died in Cherokee recently, aged 62, of chronic myocarditis.

Clifton Mather Cooley * New Britain, Conn.; Yale University School of Medicine, New Haven, 1908; vice chairman of the appeal board and a member of the draft board during World War I; served as medical examiner for the city of New Britain; affiliated with New Britain General Hospital, where he died Sept. 5, 1947, aged 66.

Okey Warren Coplin, Elizabeth, W. Va. (licensed in West Virginia in 1902); served as county health officer and county sheriff; died in St. Joseph's Hospital at Parkersburg, Oct. 6, 1947, aged 71, of cerebral hemorrhage.

James H. Edgar, Richland, Texas; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1900; died recently, aged 73, of chronic myocarditis.

Gayfree Ellison, Pawhuska, Okla.; born in Norman, Okla., June 25, 1916; University of Oklahoma School of Medicine, Oklahoma City, 1940; member of the American Medical Association; interned at Baltimore City Hospital; served two years in Europe, Africa and the Middle East during World War II; awarded the Bronze Star Medal, five battle stars and the American Defense Medal; formerly on the staff of the State Hospital in Clinton; was found dead Sept. 18, 1947, aged 31.

Robert Conway Finlay, Glen Allan, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1909; member of the American Medical Association; served on staff of King's Daughters' Hospital, Greenville; died Oct. 16, 1947, aged 63, of diabetes mellitus and obliterative endarteritis.

Minnetta C. Flinn-Jordan * Wabash, Ind.; University of Michigan Homeopathic Medical School, Ann Arbor, 1905; died Sept. 25, 1947, aged 78.

Ashby Floyd, Phenix City, Ala.; Medical Department of Tulane University of Louisiana, New Orleans, 1892; served on the school board, as city commissioner and as mayor; city recorder; died Oct. 3, 1947, aged 81.

Robert David Furlong, University City, Mo.; St. Louis University School of Medicine, 1933; served with the U. S. Public Health Service Reserve of the Coast Guard during World War II; affiliated with St. Mary's Hospital, Josephine Heitkamp Memorial Hospital, Jewish Hospital and the Missouri Baptist Hospital; died Oct. 24, 1947, aged 36, of coronary occlusion.

Paul Middleton Gamble, Albert Lea, Minn.; University of Minnesota Medical School, Minneapolis, 1924; member of the American Medical Association; died Sept. 14, 1947, aged 49, of carcinoma of the right lung.

William Ginsberg * St. Paul; University of Minnesota Medical School, Minneapolis, 1915; served overseas during World War I; major, medical reserve corps, not on active duty; on the staffs of St. Luke's, St. Joseph's and Miller hospitals; died Sept. 21, 1947, aged 57, of acute coronary occlusion and hypertension.

Hyman Maurice Glasston * Linden, N. J.; University of Vermont College of Medicine, Burlington, 1924; served during World War I; formerly physician for the board of health, board of education and fire department; for many years a trustee of the public library; served on the staffs of the Elizabeth General and St. Elizabeth's hospitals in Elizabeth, N. J.; died in New York Oct. 19, 1947, aged 47, of coronary disease.

Margaret Ann Gould * Pittsburgh; Trinity Medical College, Toronto, Canada, 1898; an Affiliate Fellow of the American Medical Association; died Oct. 30, 1947, aged 77.

Irving Greenberg * South Fallsburg, N. Y.; University and Bellevue Hospital Medical College, New York, 1917; died Oct. 13, 1947, aged 54, of cerebral hemorrhage and arteriosclerosis.

Thomas S. Grissom, Mount Pleasant, Texas; Memphis (Tenn.) Hospital Medical College, 1900; president of the Titus County Medical Society; died Sept. 27, 1947, aged 75, of congestive heart disease.

Frederick Grunwald, Louisville, Ky.; Kentucky School of Medicine, Louisville, 1898; member of the American Medical Association; served overseas during World War I; major, medical reserve corps, U. S. Army, not on active duty; for many years on the staff of the St. Mary and Elizabeth Hospital, where he died Sept. 25, 1947, aged 73.

Robert Lee Hagaman, Raymond, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1891; affiliated with the Baptist Hospital, Jackson, where he died Oct. 15, 1947, aged 81, of myocardial failure.

Allen Richmond Howard * Major, U. S. Army, retired, North Attleboro, Mass.; Cooper Medical College, San Francisco, 1911; Army Medical School, 1917; entered the medical corps as a first lieutenant in 1917; served during World War I; retired July 31, 1929 after twelve years' service; served on the staffs of the Washingtonian Hospital in Boston and the Sturdy Memorial Hospital in Attleboro; died June 4, 1947, aged 60, of coronary occlusion.

Winfred Lewis Howe, Everett, Mass.; Tufts College Medical School, Boston, 1900; member of the American Medical Association; chairman of the school committee and board of health; affiliated with the Massachusetts Memorial Hospital, Boston; died recently, aged 72, of arteriosclerotic heart disease.

Theodore Johnston * Chicago; Bennett Medical College, Chicago, 1905; formerly professor of anatomy at his alma mater; for many years physician for the Atchison, Topeka and Santa Fe Hospital Association; died in Evangelical Hospital, Oct. 12, 1947, aged 73, of chronic myocarditis and arteriosclerosis.

Wayne Theodore Killian * Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1906; professor emeritus of anesthesia at his alma mater; member of the American Society of Anesthetists; past president of the Medical Club of Philadelphia; for many years on the staff of Hahnemann Hospital, where he died Oct. 11, 1947, aged 68, of myocardial infection.

George Franklin Lamb * Grand Rapids, Mich.; University of Toronto Faculty of Medicine, Toronto, Canada, 1903; served during World War I; on the staffs of Blodgett and St. Mary's hospitals; died Oct. 6, 1947, aged 74, of carcinoma of the colon.

George Rufus Leonard, Chicago; Indiana University School of Medicine, Indianapolis, 1908; on the staff of Ravenswood Hospital; died Oct. 30, 1947, aged 70, of heart disease.

George B. Lowrie, Detroit; Detroit College of Medicine, 1900; member of the American Medical Association; for many years on the staff of the Harper Hospital; chief surgeon for the Michigan Central Railroad; served on the faculty of his alma mater; died Sept. 21, 1947, aged 73.

Orban Gayle McConnell • San Jose, Calif.; Washington University School of Medicine, St. Louis, 1924; served as a first lieutenant in the U. S. Army during World War I; medical examiner and inspector of selective service during World War II; on the staff of the O'Connor Sanitarium; died Sept. 21, 1947, aged 57, of injuries received in an automobile accident.

Edmund Johnson McNeil, Cambridge, Mass.; Tufts College Medical School, Boston, 1903; died recently, aged 75, of arteriosclerosis.

Robert Jack Mitchell • New York; Columbia University College of Physicians and Surgeons, New York, 1901; died in St. Luke's Hospital Sept. 15, 1947, aged 69.

Harold Alphonsus Murphy • Boston; Tufts College Medical School, Boston, 1915; died Sept. 23, 1947, aged 56, of carcinoma of the stomach.

Carlton Maurice Neiberg, Pittsburgh; University of Illinois College of Medicine, Chicago, 1925; specialist certified by the American Board of Orthopedic Surgery; member of the American Medical Association and American Academy of Orthopedic Surgeons; on the staffs of Columbia, Children's and Pittsburgh hospitals, died Sept. 25, 1947, aged 47.

Philip Lawrence Patrick • Marceline, Mo.; Washington University School of Medicine, St. Louis, 1902; past president of the Linn County Medical Society; served during World War I; died Sept. 19, 1946, aged 71, of cerebral hemorrhage.

James V. Prewitt, West Point, Ky.; St. Louis College of Physicians and Surgeons, 1889; died Oct. 9, 1947, aged 84, of chronic myocarditis.

John Marvin Proctor • Hot Springs National Park, Ark.; University of Tennessee Medical Department, Nashville, 1906; served as a member of the state board of health; councilor of the Seventh District of the Arkansas Medical Society; died recently, aged 69, of abdominal hemorrhage.

Charles Armand Rabethge, Randolph, Mass.; College of Physicians and Surgeons, Boston, 1891; Jefferson Medical College of Philadelphia, 1894; University of Michigan Homeopathic Medical School, Ann Arbor, 1898; died Sept. 17, 1947, aged 85.

John Dexter Rice, West Boylston, Mass.; Tufts College Medical School, Boston, 1940; interned at the Worcester City Hospital in Worcester, Mass., and served a residency at the Massachusetts Eye and Ear Infirmary in Boston; diplomate of the National Board of Medical Examiners; killed Oct. 4, 1947, aged 32, in an automobile accident near Bowling Green, Ohio.

Mary Ann Nutting-Sanborn, Meredith, N. H.; College of Physicians and Surgeons, Boston, 1890; died Sept. 6, 1947, aged 85.

John Wilson Sayer, Watertown, N. Y.; Syracuse University College of Medicine, 1935; member of the American Medical Association; interned at St. Vincent's Hospital in Staten Island and served a residency at the Flower and Fifth Avenue Hospitals in New York; on duty in the European theater of operations during World War II; found dead Sept. 25, 1947, aged 37.

Keith Sears, Trumansburg, N. Y.; Cornell University Medical College, New York, 1903; died Sept. 10, 1947, aged 70.

James M. Seliskar, Cleveland; Western Reserve University Medical Department, Cleveland, 1905; affiliated with Charity Hospital; died Sept. 23, 1947, aged 67, of arteriosclerosis.

Foster Clarke Shaffer • Douglas, Wyo.; Jefferson Medical College of Philadelphia, 1925; served as a member of the board of examiners; for eight years member of the city council; for many years a member of the school board and a health officer; died recently, aged 46, of heart disease.

Herbert D. Sterrett, Hutchinson, Kan.; Ensworth Medical College, St. Joseph, Mo., 1899; University of Kansas School of Medicine, Kansas City, Kan., 1906; died recently, aged 70, of leukemia.

August Strauch, Chicago; Medizinische Fakultät der Universität Wien, Austria, 1898; formerly on the faculty of Rush Medical College; served on the staff of Cook County Hospital; died Oct. 13, 1947, aged 74.

James Porter Strickler • Scottsdale, Pa.; Jefferson Medical College of Philadelphia, 1901; died recently, aged 69, of cerebral thrombosis.

Oscar F. Sugg, Corydon, Ky. (licensed in Tennessee in 1896); died Oct. 14, 1947, aged 88, of myocarditis.

Samuel Sullivan, Chicago; Dearborn Medical College, Chicago, 1907; served during World War I; died Oct. 8, 1947, aged 71.

Edward Eugene Terrell, Cranford, N. J.; University of Chicago School of Medicine, 1931; member of the American Medical Association; interned at the New Haven (Conn.) Hospital; formerly resident physician at the Rockefeller Institute for Medical Research in New York; served in the Southwest Pacific during World War II; for many years school physician; on the staff of the Muhlenberg Hospital in Plainfield, where he died Oct. 2, 1947, aged 44, of acute nephrosis and pneumonia.

U. G. Mitchell Walker, Flint, Texas (licensed in Texas under the Act of 1907); member of the American Medical Association; died in a hospital at Jacksonville recently, aged 77, of pulmonary edema.

Thomas John Walshe, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1897; member of the American Medical Association; served on the staffs of the Charity Hospital and the Southern Baptist Hospital, where he died recently, aged 71, of coronary thrombosis.

Joseph P. Wilson • Scottsburg, Ind.; Kentucky University Medical Department, Louisville, 1905; secretary of the Scott County Medical Society; county physician; died Sept. 23, 1947, aged 82, of coronary thrombosis.

William Price Womack, Shelbyville, Tenn; University of Tennessee College of Medicine, Memphis, 1933; interned at Baptist Memorial Hospital in Memphis; died Sept. 15, 1947, aged 43, of hypertension with acute heart failure.

DIED WHILE IN MILITARY SERVICE

Lavin Milford Andersen, Manistee, Mich.; University of Michigan Medical School, Ann Arbor, 1924; served an internship and residency at the Long Island College Hospital in Brooklyn, where he served as assistant clinical professor of radiology; formerly on the staffs of the Brooklyn Eye and Ear, the Samaritan and the Midwood hospitals, all in Brooklyn; specialist certified by the American Board of Radiology; began active duty as a major in the medical corps, Army of the United States, in October 1942; stationed at Camp Myles Standish at Taunton, Mass., and at Camp Butner, N. C., where he died Sept. 9, 1945, aged 46, following a gallbladder operation.

Melvin Denver Deck, Provo, Utah; Washington University School of Medicine, St. Louis, 1943; interned at Minneapolis General Hospital in Minneapolis; began active duty as a first lieutenant in the medical corps, Army of the United States, on March 2, 1944; stationed at the Medical Department Replacement Pool, Stark General Hospital, Charleston, S. C., with temporary duty at the Medical Field Service School, Carlisle Barracks, Pa.; relieved from duty at Stark and assigned to duty with the 133d General Hospital, Camp Gordon, Ga., in May 1944; subsequently went overseas with that unit; promoted to captain; killed in the Pacific area off Leyte Sept. 6, 1945, aged 29, while a passenger on a C-47 (skytrain) transport plane.

Emanuel Dejnozka Jr., Rock City Falls, N. Y.; born in New York, July 26, 1916; Albany Medical College, 1942; diplomate of the National Board of Medical Examiners; interned at Misericordia Hospital in New York; appointed first lieutenant in the medical department, Army of the United States, June 4, 1942 and began active duty July 3, 1943; assigned to Station Hospital and the 3706th Army Air Forces Base Unit at Sheppard Field, Texas; promoted to captain; on July 9, 1945 arrived in the European theater of operations, where he was assigned to headquarters, 9th Air Disarmament Group, 53d Air Disarmament Squadron and 1515th Quartermaster Battalion; died Dec. 4, 1945, aged 29, of injuries received when the ambulance in which he was riding near Walsdorf, Germany, skidded and went over an embankment.

Homer LaFayette Hobbs, Greensboro, N. C.; Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, N. C., 1944; interned at the Paterson (N. J.) General Hospital; entered the medical corps of the Army of the United States as a first lieutenant on July 6, 1945; killed in an automobile accident in Harrisburg, Pa., April 16, 1946, aged 27.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Nov. 30, 1947.

The British Medical Association and the National Health Service

In a letter to the *Daily Telegraph* Sir Ernest Graham-Little, dermatologist and member of Parliament, who is the great protagonist of a state medical service, has summed up the present position. He first points out the reluctant consent of the Minister of Health, Mr. Bevan, to consult with the members of the medical profession on the scheme. As he sees it, the medical profession, under the leadership of the British Medical Association, demands a radical amendment of the National Health Service Act as a preliminary to accepting service under the act. It is therefore important to consider the strength and influence of the British Medical Association. Four years ago its membership was about 40,000; today it is 56,000. Some 70,000 practitioners are on the medical register, but only about 50,000 are in practice. It is clear that the present membership includes practically all those who are in active practice, a record of special significance, as membership is voluntary.

The promised medical service will call for medical staffing twice or thrice as large as the existing number of active practitioners. It takes six years to train a general practitioner and from ten to twelve years to train a specialist. Thus the law cannot be properly enforced for two or three decades, if at all. Meanwhile, the existing health services, admitted to be among the best in the world, will be completely disrupted. Therefore it is not surprising that Mr. Bevan should be reluctant to disclose the actual available resources with which he proposes to launch the act within the next eight months. The National Health Service is now law, and the government proposes to put it into operation soon, but negotiations between the British Medical Association and the government are still proceeding. These have not been disclosed, though concern regarding them has been expressed. The medical profession has been assured that its representatives are making a firm stand on the demand that the act should be amended according to its wishes. The increased membership of the British Medical Association, due to apprehensions aroused in the profession by attempts to socialize the practice of medicine, has strengthened its position in its struggle with the government. Its claim to represent practically the whole active membership of the profession cannot now be gainsaid.

Research on Cancer

At the annual meeting of the British Empire Cancer Campaign the Duke of Gloucester stated that \$540,000, a record sum, had been collected in the past financial year. If additional funds were available progress could be greatly speeded up; more of the best brains in the Empire could be attracted to cancer research, and the equipment of research centers could be much improved—all of which would go far toward hastening the conquest of cancer, which is now the chief killing disease. The number of deaths due to cancer of the lung have increased sixteen and one-half times in men and eight times in women since 1921, although the incidence of cancer of the larynx has not increased in either sex in the last fifteen years. Some authorities consider that the apparent increase in cancer of the lung is due wholly to improved methods of diagnosis, while others emphasize the high proportion of error which allows over 40 per cent of cases to escape diagnosis even under the best conditions of hospital practice. The examination of sixty-five occupations has disclosed none which account for any large fraction of the increase of deaths attributed to cancer of the lung.

The Journal of Clinical Pathology

The British Medical Association announces the publication of a new periodical, the *Journal of Clinical Pathology*. It will consist of original articles, reviews, technical methods and abstracts which will be useful to practicing clinical pathologists, whose chief concern is to elucidate disease in man. The editor is Dr. A. Gordon Signy, who has been appointed by the Association of Clinical Pathologists. The journal will be published quarterly, and the subscription is \$6 per annum.

The Virus Question

Lord Horder said that a special committee has been set up to develop research into the whole position of virus in relation to cancer, and a grant of \$100,000 has been set aside for the purpose. The view that cancer lay outside the scope of chemotherapy was probably premature. Recent work has been quite hopeful, and the campaign appointed another special committee to organize research in this field. In the field of physics atomic energy has brought new tools of use in research and treatment.

Effect of Ascorbic Acid on Intradermal Tuberculin Reaction

At a meeting of the Ferrara section of the Italian Society of Experimental Biology, Dr. C. Mattei, of the Institute of Medical Pathology of the University of Ferrara, reported on the changes in the intradermal tuberculin reaction in persons to whom ascorbic acid had been administered. His research was aimed to demonstrate one aspect of the immunizing action of ascorbic acid. The method employed was to produce on one forearm an intradermal reaction with Koch's old tuberculin before treatment with ascorbic acid and to produce an analogous elevated patch on the other forearm with distilled water. At intervals of fifteen minutes, twelve hours and twenty-four hours, the outline of the zone was examined through a small sheet of cellophane; an elevated red spot was clearly visible. The area involved was measured. The number indicating in millimeters the extent of the elevated patch has been defined as the "tuberculin value." Then the organism was loaded with ascorbic acid by intravenous administration, until a state of saturation was reached, as determined by the amount of ascorbic acid excreted daily in the urine, using dichlorophenolindophenol.

Treatment was given to 21 patients divided in three groups: patients with hepatic disorders, patients with tuberculosis and patients with various disorders. All the patients had suffered with malaria. Results were as follows: in the group with hepatic disorders the medium tuberculin value was increased from 61 before the administration of ascorbic acid to 140 after its administration (140 per cent). In the group with tuberculosis the increase was from 61 to 84 (38 per cent), and in the group with various disorders from 99 to 163 (65 per cent). In only 5 of the 21 patients who were treated was a reduction of the tuberculin values observed with medium variations of less than 35 per cent.

The results of Mattei's research thus demonstrated that in the majority of cases the saturation of the organism with ascorbic acid determined an increase in the intensity of the intradermal reaction after the injection of tuberculin.

Sulfonamide Compounds and Penicillin

At a meeting of the Roman Medicosurgical Association in Ravenna, Dr. L. Fontana presented the results obtained by him with sulfonamide compounds and penicillin when administered by the intrapleural and the intra-articular route. The speaker reported highly satisfactory results in many cases, even of the multilocular type, of empyema by means of intrapleural injection.

tions of sulfonamide compounds (sulfapyridine and sulfathiazole) after previous removal of a certain amount of pus. He reported instances of definite and fairly rapid recovery. After penicillin came on the market, Dr. Fontana adopted the intrapleural injection in doses of 50,000 to 100,000 units combined in general with the administration of sulfonamide compounds, and he has obtained highly satisfactory results. For pulmonary abscess and gangrene the speaker considered penicillin by the endobronchial route and by means of bronchoscopy the method of choice, particularly in the many cases which are inaccessible by the transthoracic route, but he did not have direct experience. Excellent results were obtained also in cases of suppurative arthritis with intra-articular injections of sulfonamide compounds or penicillin after previous removal of pus. Rapid and definite improvement occurred with few and temporary functional residues.

Dr. Galassi reported the results obtained with transthoracic intrafocal injections of penicillin in the treatment of pulmonary abscess. The technic was in principle the same as that used by other authors, i. e., entering the lung under roentgenologic control and from there the cavity of the abscess. Among the inconveniences manifested during such trials, the most important was the production of a pneumothorax in 1 instance, which, however, subsided spontaneously within a short time. From the small number of cases so far observed, Dr. Galassi has not been able to draw definite conclusions, but he considers the intrafocal treatment of pulmonary abscess with penicillin as promising.

SPAIN

MADRID, Nov. 18, 1947.

History of Anatomy

At the Madrid Medical Association, an interesting course of lectures has been given by Dr. P. Lain Entralgo, who has brilliantly succeeded in the Chair of History of Medicine of the Madrid Faculty the now retired Dr. E. Garcia del Real. The object was to present Dr. Lain's concept of the historical evolution of anatomy, whose basic stages are represented, according to him, by Galenus, Vesalius, Bichat, Virchow and Gegenbaur, passing through the interlude of Testut, to end in Braus's "Anatomie des Menschen."

In his survey Lain passed successively through the following considerations: if the anatomist proposes to describe the external appearance and the internal structure of man, it is evident that man presents two fundamental constituent signs: the external and internal form of the body and the movement of that body which displays his living activity, which signs had perforce to mark rules, norms of thought, for the first Greek anatomists. Hence the first anatomic vision, faithful to the cultural lines of Greece, was that of Galenus, who described the body as a living anatomy.

The following stage is represented by Vesalius, who, during the Italian Renaissance and himself a perfect dissector of (motionless) corpses, describes these as though they were immobile statues with only potential movement. Therefore his anatomic concept is architectural and static. For this reason, he—an innovator in anatomy but a traditionalist in physiology—describes, in his "De Fabrica Humani Corporis," the human statue as potentially—only potentially—animated by the three old *Dynameis* of classical physiology.

That static anatomic body of Vesalius' is first put into movement by the physiologists, who appear in the course of time: Fabricius ab Aquapendente, Sanctorius, Harvey and Borelli. The forces and laws which will put it into operation will no longer be Galenus's old *Dynameis* but those indicated by the new physiologic knowledge.

In the eighteenth century Bichat begins to see the body no longer as a static unit ready to move but as a whole composed

of parts, which are the tissues, harmoniously related in the vital conjunction. What in Vesalius was an architectural element is replaced in Bichat by the tissues of every element, in which reside the specific forces of the vital activity.

Fifty years later Virchow, with the microscope already available and two contributions brought by time: the genetic idea and individualism—which will act and influence him as the atmosphere of the time—will see a cell where Bichat saw a tissue. Cellular pathology, which Virchow explains, is, Lain said: "a federal republic of vital units: the cells grouped into tissues, organs and systems." Bichat and, above all, Virchow then attempt to give an analytic explanation in exclusively anatomic descriptions, forgetting the real form of the body as the human eye sees it.

In this situation Gegenbaur appeared, "the anatomist who most genuinely projected on anatomic description the idea of the evolution of living beings," "making anatomy scientific by means of genetic explanation" without giving up the cellular theory. Gegenbaur focused anatomic study, investigating the steps made by the body previously, and came to conceive the human body—its form—as "the occasional and transitory state of an evolution, of a progressive process toward more complex and perfect biologic states." But Gegenbaur proceeded in the Vesalian manner: he studied the parts of the body, the organs and the tissues, separately in the first chapters of his work.

From this panoramic view of Lain's we infer that Galenus, Vesalius, Bichat, Virchow and Gegenbaur are the representatives of the various ways of looking at the human body throughout history and that their names may be used to designate the respective interpretations: each of them represents in anatomy the cultural panorama of the respective historical situation, not only because the means of observation were different at every moment in history but because the descriptive mentality of each period differed.

The anatomic vision of today is not, according to Lain, that of Testut, which looks like a game, but that represented by Braus. Braus's "Anatomy" is, in a certain way, a "return to Galenus"—his descriptive point of view is functional or physiologic—although, naturally, without giving up the ulterior tectologic and evaluative points of view. Braus attempts, not always successfully, to reduce to systematic unity the functional, tectologic and genetic consideration of human anatomy.

This course was attended by large audiences who listened to Professor Lain Entralgo with evident admiration. In the Spanish medical culture of the present, Lain Entralgo represents the intellectual sign of the times, giving to the history of medicine intellectual and philosophic contents which, at his age, can only be found in one as well endowed personally as he is.

These data are advanced to readers of THE JOURNAL because of the great interest awakened by their exposition in the Spanish public, always avid for weighty concepts, and because of the impetus now being given to historical studies by this master who is little known abroad.

Of his lectures, he has so far published monographically only the one on Bichat.

Congress of Digestive Pathology and Nutrition

The fifth Spanish Congress of Digestive Pathology and Nutrition was held in Saragossa October 26-30. The first report was read by Dr. C. Jimenez Diaz, professor in the Madrid Faculty of Medicine, and his collaborator Dr. Marina Fiol on "Chronic Enteropathy of the Liver." More about this paper will appear in another letter, because it was of great interest.

The second report, by Professor J. Andreu Urrea, of Seville University, dealt with "The Influence of the Midbrain and the Pituitary Body on Glucide Metabolism." Dr. Andreu summed up his experimental work of a number of years, coming to highly interesting conclusions.

The subject "Problems of Chronic Appendicitis" was expounded by Drs. Pinos and Piñiguera, and the fourth report, by Professor G. Marañon, on "Thinness, Its Pathogenesis and Treatment" was read in summarized form by Dr. Gutierrez Arrese in the author's absence.

During the congress, meetings were held by the sections of digestive pathology, nutrition, surgery and therapeutics and diagnosis, in the course of which some two hundred communications were heard.

Professor Bonorino Udaondo, of the Buenos Aires (Argentina) Faculty of Medicine, lectured on "Intestinal Polyposis"; Professor Teófilo Hernando on "Intestinal Tuberculosis," and Dr. Callar Mones, of Barcelona, on "Medical and Surgical Treatment of Gastroduodenal Ulcer." The Congress had an extraordinarily large attendance of specialists. The next congress will be in Santander in 1950.

Improvements at Seville

The Seville Faculty of Medicine has been greatly improved. About a year ago an Institute of Anatomy was opened, and now another building is being erected to house the Departments of Physiology, Biochemistry, Pharmacology and Microbiology. Another building is under construction for a new Polyclinic Institute. Although the Old Central Hospital annexed to the Faculty of Medicine is out of date, it is being gradually renewed. Nevertheless, the city still lacks a modern hospital such as a university city of its rank should have.

The most significant work done in the Medical Schools of Seville University in recent years is that of Professor J. Andreu Urrea's School, on clinical and experimental lines, on the influence of the midbrain and the pituitary body in carbohydrate metabolism. Dr. Andreu directs an excellent school in which studies are conducted notwithstanding the difficulties arising from a shortage of materials. In his school papers have also been published on the origin of the proteins of the plasma (Dr. Villar and collaborators) and on intestinal absorption (Dr. Leon Castro); another is now being prepared by the latter author on immunity.

The Seville Royal Academy of Medicine, whose president is Dr. Dominguez Rodino, maintains a permanent state of activity, being a center for meetings and lectures, and so does the Seville Royal Medical Society of Hospitals, which was directed by Professor P. Rodrigo Sabalette up to the time of his death.

To sum up, the medical scientific activity of Seville is on the increase and carries on at a promising pace. It is expected that when material contributions and working conditions improve the Seville Schools will attain to the greatest fame in Spain.

Professor P. Rodrigo Sabalette

In the terrible explosion in the torpedo dump at the Cadiz naval yards, Professor P. Rodrigo Sabalette died in the prime of life with two of his sons. Professor Rodrigo Sabalette was one of the most distinguished figures in Spanish medicine. A son of Professor L. Rodrigo Lavin (a great Spanish physiologist who, at 80 years of age, is thus bereft) he studied in England and Germany mostly on problems of neurologic physiology. In recent years he wrote the chapters on Diseases of the Nervous System in the "Treatise of Medical Pathology" published under the editorship of Professor M. Banuelos, in which he displayed a deep didactic sense and magnificent clinical and therapeutic training and knowledge. He was the author of a monograph on "Cancer of the Lung" and of an excellent paper on "Slow Endocarditis and Sepsis," and his last papers, on brain tumors, still unpublished, represent a notable advance in this field. He was an exemplary member of Spanish university life, and his fine character enabled him to overcome great difficulties in his profession. His fellow workers and pupils, who owed so much to the chivalrous conduct and teaching of this great master, will not easily find another to replace him.

BCG Vaccination in European Countries by the Danish Red Cross

Since BCG vaccination was first adopted in Denmark in 1927, this measure has proved so effective that the vaccine has lately become an article for export, witness the work of Danish BCG teams in Poland, Yugoslavia, Hungary, Austria and the American and British zones in Germany. Each of these Red Cross teams consists of one physician and two nurses, and it is hoped that the present number of fifteen teams will ultimately be quadrupled. But as Denmark alone cannot provide as many as sixty doctors trained in BCG vaccination, some of the newer teams must be staffed by members who have come from the aforementioned countries to study the highly specialized anti-tuberculosis work in Denmark. It is hoped that Norway also will supply a certain number of BCG specialists. In the past half year about half a million persons have already been vaccinated, and in Yugoslavia, where the Danes have worked for nine months, the government has now taken over this work. In Poland, the first country visited by the Danish teams, practically every one over the age of 25 was found to be tuberculin positive and was therefore not eligible for BCG vaccination. Accordingly, attention is being concentrated on persons under this age. The Danish Red Cross enjoys the active support of the Danish Public Health Service and of the State Serum Institute in Copenhagen. The sum of 3,500,000 kroner has been earmarked by the Danish Red Cross for BCG vaccination abroad, and three aeroplanes have been purchased for the supply of fresh vaccine at short intervals to the various centers in which the teams happen to be working. It is calculated that the cost per head of this measure is only $\frac{1}{2}$ krone (50 öre) and that each team can deal with 1,500 to 2,000 persons every day. The goal which has been set by the Danish Red Cross is a total of 1,000,000 vaccinations per month.

The Wartime Rise in the Danish Birth Rate

Why did the Danish birth rate rocket up during the war in spite of shortages of food, fuel, houses, domestic servants and much else supposed to influence fertility? In an attempt to answer this question, Carry Hedemann quotes the following figures: In 1939 there were 67,900 births and in 1940 there were 70,100. By 1946 this figure had jumped to 96,000. At this rate there would have been some 100,000 live births annually in a short time, but from August 1946 onward there was a decline instead of a further rise. Was the wartime rise due to the blackout and other restrictions which made married couples more homebound than in peacetime? But in Sweden, where the birth rate also rose definitely during the war, there was no blackout or "house arrest" forcing married couples to remain at home. Did the German troops contribute appreciably to the rise in the birth rate? To be sure, they sired some 4,000 to 5,000 children in Denmark, but these figures are but a small fraction of the total rise. Was it due to a passing vogue, the bearing of many children having become rather fashionable instead of a stupendous mistake and disgrace? What is plain is that the knowledge of contraceptives acquired by the public has not had such a devastating effect on the birth rate as their opponents would have us believe. High wages and a resulting sense of social security may well have played an important part, and with all these and many other factors possibly influencing the birth rate, we must deny ourselves the luxury of clearcut conclusions, contenting ourselves with the undeniable fact that the Danish birth rate went up during the war by leaps and bounds.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in *THE JOURNAL*, Jan. 3, page 58.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Examination*. Montgomery, June 22-24, 1948. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery 4.

ALASKA: * *Juneau*, March 2. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

ARKANSAS: * *Examination*. Little Rock, June 3-4. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana.

CALIFORNIA: *Oral*. San Francisco, Jan. 17-18; Los Angeles, Feb. 28-29. *Written Examination*. Los Angeles, March 1-4. *Oral and Clinical Examination for Foreign Graduates*. Los Angeles, Feb. 29; San Francisco, June 6. Sec., Dr. Frederick N. Scatena, 1020 N Street, Sacramento 14.

CONNECTICUT: * *Examination*. March 9-10. Sec., Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic Examination*. Derby, March 9-10. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

DELAWARE: *Examination*. Dover, Jan. 13-15. *Endorsement*. Dover, Jan. 20. Sec., Dr. J. S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: * *Reciprocity*. Washington, D. C., March 8. Sec., Commission on Licensure, Dr. G. C. Ruhland, 4130 E Municipal Bldg., Washington.

FLORIDA: * *Examination*. Jacksonville, June 29-30. *Reciprocity*. Jacksonville, June 28. Sec., Dr. Harold D. Van Schaick, 6675 Windsor Lane, La Gorce Island, Miami Beach 41.

HAWAII: *Examination*. Honolulu, Jan. 12-15, 1948. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu, T. H.

IDAHO: Boise, Jan. 13-15. Sec., Miss Estella S. Mulliner, 355 State House, Boise.

INDIANA: *Examination*. Indianapolis, June 1948. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, K of P Bldg., Indianapolis.

IOWA: * *Examination*. Iowa City, March 15-17. Comm., Dr. Walter L. Biering, Dept. of Health, Des Moines.

KANSAS: Kansas City, June 9-10. Sec., Board of Medical Registration & Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: *Examination*. Louisville, June 16-18. Sec., Dr. P. E. Blackerby, 620 S. 3d St., Louisville.

MAINE: Portland, March 9-10. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

MARYLAND: *Medical Examination*. Baltimore, June 15-18. Sec.-Treas., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic Examination*. Baltimore, June 15-16. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: *Examination*. Boston, March 9-12. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413 E State House, Boston.

MINNESOTA: * *Minneapolis*, Jan. 20-22. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

MISSISSIPPI: Jackson, June 1948. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MISSOURI: *Examination*. Kansas City, Jan. 19-21. Exec. Sec., Mr. John A. Hailey, P. O. Box 4, State Capitol Bldg., Jefferson City.

MONTANA: Helena, April 5-7. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

NEVADA: Carson City, May 3. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: *Examination*. Concord, March 11-12. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

NEW JERSEY: *Examination*. Trenton, June 15-17. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW YORK: *Examination*. Albany, Buffalo, New York, Syracuse, Feb. 16-19. Sec., Dr. J. L. Lochner, Jr., Education Bldg., Albany.

NORTH CAROLINA: *Endorsement*. Pinehurst, Jan. 12. Sec., Ivan Procter, 236 Hillsboro St., Raleigh.

OHIO: *Endorsement*. Columbus, April 6. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

PENNSYLVANIA: *Examination*. Philadelphia, Jan. 13-16, 1948. Acting Sec., Board of Medical Education and Licensure. Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

SOUTH CAROLINA: *Written Examination*. Columbia, June 21-23. *Endorsement*. Feb. 2. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

SOUTH DAKOTA: * *Pierre*, Jan. 20. Sec., State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

TEXAS: Austin, Feb. 19-21. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

UTAH: *Examination*. Salt Lake City, June, 1948. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

VERMONT: *Examination*. Burlington, Feb. 5-6. Sec., Dr. F. J. Lawless, Richmond.

WASHINGTON: * *Examination*. Seattle, Jan. 19-21. Sec., Dept. of Licenses, Miss Virginia Wotherspoon, Olympia.

WEST VIRGINIA: Charleston, Jan. 12-14. Comm., Public Health Council, Dr. N. H. Dyer, State Capitol, Charleston 5.

WISCONSIN: * *Examination*. Madison, Jan. 13-15. *Reciprocity Oral*. Madison, Jan. 14. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

WYOMING: *Examination*. Cheyenne, Feb. 2. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ALASKA: Juneau, Feb. 23-29. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

DISTRICT OF COLUMBIA: *Examination*. Washington, April 19-20. Sec., Dr. G. C. Ruhland, 4130 Municipal Bldg., Washington.

FLORIDA: *Examination*. June 5. Final date for filing application is May 23. Sec., Mr. M. W. Emmel, Univ. of Florida, Gainesville.

IOWA: Des Moines, Jan. 13, April 13, July 13, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

NEBRASKA: *Examination*. Omaha, Jan. 13-14. Dir., Dept. of Health, Mr. Oscar F. Humble, Room 1009, State Capitol Bldg., Lincoln 9.

OKLAHOMA: Spring 1948. Sec., Dr. Frank Clinton Gallahe, 813 Braniff Bldg., Oklahoma City.

OREGON: *Examination*. Portland, March 6. Sec., Basic Science Examining Committee, Mr. C. D. Byrne, Univ. of Oregon, Eugene.

WASHINGTON: *Examination*. Seattle, Jan. 14-15. Sec., Dept. of Licenses, Miss Virginia Wotherspoon, Olympia.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Husband's Action for Loss of Services of Wife Caused by Malpractice.—The plaintiff filed suit for damages for loss of the services and companionship of his wife alleged to have been caused by the malpractice of the defendant physician. From an unfavorable ruling of the trial court, the defendant appealed to the Supreme Court of North Dakota.

In 1943 the defendant physician was engaged to take care of the plaintiff's wife during her pregnancy. Shortly before the time for delivery, which was to be by caesarean operation, the defendant advised the plaintiff's wife that she would not be able to have another baby except by caesarean operation and that a second or successive operation would be dangerous and detrimental to her health. Accordingly it was agreed that the defendant would perform a sterilization operation on the wife at the time of the delivery. This was done and the defendant was paid his fee therefor, the defendant representing that the operation had been successfully and properly performed. Subsequently the plaintiff and his wife, relying on the representation of the defendant and believing that he had properly performed such operation, engaged in normal sexual intercourse and in 1945 the wife again became pregnant. It was again necessary to make delivery by caesarean operation, and the wife suffered such loss of blood therefrom as to require blood transfusions and to gravely endanger her life. The second caesarean operation and the birth of the second child, in addition to the fear and shock suffered by the plaintiff's wife on discovering that the sterilization operation had been a failure, that she was pregnant and that she would again be compelled to have a caesarean operation, permanently impaired her health and rendered her highly nervous and mentally and physically unstable. As a result thereof the plaintiff was compelled to expend a considerable amount of money for medical and hospital care and nursing services for his wife and was and will be deprived of the services and companionship of his wife for a long time—all as a consequence, it is alleged, of the defendant's failure to perform the sterilization operation in a proper and skilful manner.

The defendant physician admitted that he was engaged to perform the medical and surgical services referred to but denied that they were performed negligently or carelessly. He further alleged that the statute of limitations provides, among other things, that actions for the recovery of damages resulting from malpractice must be commenced within two years after the cause of action has accrued, that this is an action for malpractice, that the cause of action accrued at the time the alleged

negligent operation was performed on or about March 16, 1943 and that inasmuch as defendant's services as a physician and surgeon terminated prior to April 1, 1943 and this action was not brought until Nov. 10, 1945 it is barred by the statute.

The court discussed the distinction between an action for malpractice which accrues to the wife and an action for damages for loss of the wife's services because of such malpractice which accrues to the husband. Among other things, the court said that the gist of the husband's cause of action is the loss and expense sustained by him, and not the injuries sustained by her, even though her injuries were caused by the wrongful acts or negligence of another. Such loss and expense sustained by him are not merely items of damages but are essential to the cause of action itself. The two liabilities are distinct. Thus, the fact that the statute of limitations has run against the wife's cause of action will not necessarily prevent the husband from prosecuting his. A cause of action does not accrue, said the court, until the party owning it is entitled to begin and prosecute an action thereon; it accrues at the moment when he has a legal right to sue on it and no earlier. A husband has no right of action for the loss of services, society and companionship of his wife and incidental expense for her treatment and care until the loss of services, society and companionship actually occurs. The negligence of the defendant physician in the performance of the operation on the plaintiff's wife was an invasion of her rights, and any injury sustained by her as a result thereof constituted a tort on her but did not constitute a tort on the plaintiff. The actionable wrong against the plaintiff was the interference with his marital rights, depriving him of his wife's services, society and companionship and requiring expenditures by him for her medical treatment and care. These do not constitute mere items of damage in an action for negligence. They are essential to the cause of action itself, which cannot arise until such consequences have followed the injury.

According to the complaint the plaintiff's wife gave birth to a child on March 7, 1945. The loss of services, society and companionship and expenditures for medical treatment and care occurred after the plaintiff's wife became pregnant with the child so born on March 7, 1945. The present action was commenced Nov. 10, 1945, within two years after the plaintiff's cause of action accrued. The Supreme Court therefore held that the order of the trial court overruling the defendant's defense of the statute of limitations was proper.—*Milde v. Leigh*, 28 N. W. (2d) 530 (N. D., 1947).

Workmen's Compensation Acts: Employer's Liability for Physician's Malpractice.—The claimant was granted an award for compensation for an alleged industrial accident so the defendant industrial commission appealed to the Supreme Court of Colorado.

The claimant, a waitress handling food in a local restaurant, was directed by her employer to secure a health certificate and submitted herself to examination by a physician, who drew from her arm some blood for the purpose of making a blood test required by law. The lesion made by the physician became infected, and as a result of the disability thus created she was forced to leave her employment.

It is admitted that the claimant did sustain a physical injury and that it was the result of an accident. Whether or not this accident "arose out of and in the course of her employment," however, depends on the circumstances under which she submitted to the blood test.

The evidence showed that the claimant and other employees were ordered by their employer to have a blood test made. They were not directed to go to any particular physician but were advised that if they went to a certain doctor the charge for the tests would be \$2 each. The claimant went to a physician of her own choosing for the test. The Colorado general assembly created the State Board of Health, which it empowered "To establish a uniform code of sanitary rules and regulations for the preparation, sale and serving of food." It also provided that the code of sanitary rules and regulations include medical examination of all restaurant employees handling food. Regulation 6 of the state board's laws, rules and regulations provides: "All persons engaged in the handling and preparation of food shall obtain a permit card from the State Board of Health. Application for a permit card shall be made on a form furnished

by the board and shall include a report from a licensed physician stating that the applicant has been examined and found free of communicable disease. Examinations shall include a blood test and other laboratory reports as indicated."

It is apparent, said the court, that the employer was obligated by the state law to have the claimant obtain a health certificate. It was not his regulation or requirement, it was that of the state. The claimant was incapacitated by reason of her compliance therewith. Obviously, as the commission found, her accident did not arise out of and in the course of her employment. Continuing, the court said that it had found no cases involving the question here presented, but that cases where employees have been injured as a result of vaccination or inoculation present similar legal problems. What they hold is, that the right to compensation is determined by the construction placed on the phrase, "arising out of and in the course of employment," and its application to the facts in each particular case. Compensation was allowed in those cases in which the vaccination or inoculation was performed for the benefit of the employer and had been required by him. On the other hand, compensation was denied in those cases where it appeared that vaccination or inoculation was made necessary by reason of public requirement.

In the instant case the claimant was ordered by her employer to take the blood test but this he was legally obligated to do under the statute. The commission was right in finding that the claimant's accident did not arise out of and in the course of her employment. Accordingly the judgment in favor of the claimant was reversed.—*Industrial Commission v. Messinger*, 181 P. (2d) 816 (Colo., 1947).

Drunkenness: Admissibility in Evidence of Chemical Test Showing Amount of Alcohol in Blood.—The defendant was charged with a negligent homicide as a result of his operation of a motor vehicle. From a judgment of guilty and sentence thereon, the defendant appealed to the Municipal Court of Appeals for the District of Columbia.

While the defendant was at a hospital following the automobile accident, he was asked for a specimen of his urine, which could be tested to determine whether or not he was under the influence of alcohol at the time of the accident. One of the police officers warned him that the results of such a test could be used for or against him. The defendant then gave the specimen. At the trial the specimen was produced, properly identified, and the results of the test were admitted in evidence, over objection by the defendant. According to expert testimony the tests showed 0.22 per cent alcohol and established that the defendant was under the influence of alcohol at the time. The defendant did not contend that the specimen was not given voluntarily (there is absolutely no showing of duress, intimidation or entrapment) but that the giving of the specimen was the equivalent of a confession and was therefore protected by the privilege of the Fifth Amendment against self incrimination. In *Novak v. District of Columbia*, 49 A. (2d) 88, J. A. M. A. 134:208 (May 10, 1947), which involved a rather analogous situation, the court did not decide whether the giving of the specimen for analysis was the same, from an evidentiary standpoint, as making a statement or confession. In the present case the Municipal Court of Appeals said that it must now decide the question on which it reserved decision in the Novak case. We hold, said the Court of Appeals, that in taking the specimen there was no violation of any rights guaranteed by the Constitution. The whole history of the privilege against self incrimination shows that it was designed to protect against testimonial compulsion. There was no such compulsion here. The evidence sought was whether the accused was under the influence of alcohol. He does not claim that the scientific test was inaccurate or that the results of the test were incorrectly interpreted. What is obtained from the accused by such action is not testimony about his body, said the court, but his body itself, or as here, fluid or secretions of his body. There seems to be no question that when such a specimen is given voluntarily the analysis thereof is admissible. The Court of Appeals therefore held that the evidence concerning the urinalysis was properly admitted in the trial court and that the judgment of the trial court be affirmed.—*Ridgell v. United States*, 54 A. (2d) 679 (D. C., 1947).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Spinal Cord Injuries: Automatic Micturition.—The observations presented by Martin and Davis are based on an experience with 471 patients with injuries of the spinal cord. The establishment of efficient urinary function is one of the primary goals in the care of the patient with an injury of the spinal cord. Urinary function in the patients observed by Martin and Davis has appeared in one of the following five forms: (1) early return to normal micturition; (2) eventual return of partial voluntary control of micturition; (3) involuntary dribbling of urine, or the frequent uncontrolled passage of small amounts of urine; (4) absolute retention, a less common situation, and (5) automatic or reflex micturition. If complete normal urinary control or partial voluntary control aided by special efforts on the part of the patient to empty his bladder cannot be obtained, the ideal condition is that of automatic micturition. In numerous instances the authors have found proof of the efficacy of the indwelling catheter with tidal drainage not only in the establishment of automatic micturition but also as an aid in restoring partial voluntary control. In no case did automatic micturition develop while a suprapubic catheter was in place. On the contrary, many patients developed such urinary control following the removal of the suprapubic tube, placement of an indwelling catheter and training for a period of time thereafter with tidal drainage or with carefully

controlled manual drainage. Automatic micturition will develop following a complete lesion at any level within the spinal cord or cauda equina. It does not appear in the presence of incomplete lesions of the cord. Cystometric examination at regular intervals will indicate when the catheter may be removed to allow the trial of automatic micturition, indicating that a reflex response to tension of the bladder wall is necessary for this activity. Automatic micturition will develop only when there is no mechanical obstruction of the neck of the bladder and when the sphincter is capable of reflex relaxation. Extravesical stimuli are an aid but not a necessity to the development and maintenance of automatic micturition. Automaticity will not develop in the patient with severe bladder sepsis, multiple calculi or severe debilitation.

Experimental Gas Gangrene: Preliminary Report.—Altmeier and his associates studied the possibilities of producing effective toxoid immunity against a severe form of experimental gas gangrene developed in the presence of crushed muscle and dirt in animals whose susceptibility and antigenic response are similar to those of human subjects. The studies were made on 364 guinea pigs, which were injected with Clostridium welchii toxoid and were then challenged at various intervals after the injection of the toxoid. The degree of protection was low in the early experiments, being 12 and 33 per cent, although blood antitoxin levels in excess of 0.1 unit per cubic centimeter were produced before challenge. When similar groups of animals were challenged with injections of toxin or bacterial culture into healthy muscle, 80 to 100 per cent of the animals were protected by blood levels in excess of 0.1 units per cubic centimeter. In subsequent experiments, however, modified procedures of immunization with toxoid have gradually increased the protection to 50 to 100 per cent of animals. The presence of an unknown factor or factors which contribute to the toxemia and mortality of experimental gas infection developing in the presence of crushed muscle and dirt is suggested by these studies. A high degree of immunity is possible by the injection of toxoid against gas gangrene produced by Cl. welchii, but the duration of the immunity is undetermined. Other studies are in progress to increase and extend the degree of immunity afforded by injections of Cl. welchii toxoid and to produce similar immunization with toxoids of the other clostridia associated with gas gangrene in anticipation of the development of an effective mixed toxoid for human prophylaxis against clinical gas gangrene.

Factors Limiting Surgery for Hypertension.—According to Heinbecker, the surgical treatment of essential hypertension has been based on the concept that it is due to overaction of the sympathetic nervous system. The increased activity of the sympathetic nervous system has been pictured as causing general or local vasoconstriction and an increased secretion of epinephrine. More recently such overaction has been regarded as responsible for the constriction of the renal blood vessels, thus leading to a release of renin. The author presents evidence that a humoral mechanism, not overaction of the sympathetic nervous system, is the primary cause of essential hypertension. It is postulated that in man hypophyseal eosinophil cell overaction with a resultant trophic stimulation of the adrenal cortex as the result of functional depression of the hypothalamic nuclei innervating the neural hypophysis is the primary cause of essential hypertension. The only two organs capable of releasing humors concerned with the pathogenesis and symptomatology of hypertension and whose function can be modified by sympathectomy are the kidneys and the adrenals. Any beneficial effect to be obtained by removal of portions of the sympathetic nervous system in the treatment of essential hypertension is to be obtained when such removal results in a denervation of the adrenals and the kidneys. The removal of portions of the sympathetic nervous system more extensive than is required for denervation of the adrenals and the kidneys is unnecessary. The temporarily greater enlargement of the vascular bed effected by this means may cause a shunting of blood from the kidneys sufficient to impair their function and thereby, through the release of renin, accelerate the degenerative changes in the extrarenal blood vessels.

Ocular Involvement (I and II) in Rats on Deficient Diets.—Ferraro and his co-workers observed that most rats on tryptophan-deficient diets showed arrest of growth, loss of body weight, disappearance of the subcutaneous adipose tissue, alteration of fur, atrophy of the gonads and, at times, yellowish coloring of the incisor teeth with alteration of the enamel. Ocular changes in young animals included spectacle eyes, conjunctivitis, superficial vascularization of the cornea and occasionally cataractous changes in the lens. This group of animals did not live long on the deficient diet and generally died before presenting the more specific symptoms of tryptophan deficiency. In more mature rats spectacle eyes were apparent at times, but less frequently and to a lesser degree than in the younger group. However, corneal vascularization and, particularly, various degrees of cataractous changes in the lens were more constant. In adult rats, spectacle eyes and conjunctivitis were only occasionally noted, whereas vascularization of the cornea was more commonly observed. In rats maintained on a valine deficient diet the corneal changes seem to be the result of edema and progressive degeneration, leading gradually to keratinization and disorganization of the epithelial structure of the cornea. In addition, pronounced deep vascularization of the cornea is observed. Slight changes in the lens, characterized chiefly by vacuolation of the cortex, are only occasionally noted. These structural changes in the eye appear to be reversible (if treated in time), as demonstrated by notable improvement following the administration of synthetic valine to the animals on a valine deficient diet.

Melkersson's Syndrome.—Kettel reports 5 cases of Melkersson's syndrome in 2 young men aged 16 and 18 years respectively and in 3 women between the ages of 30 and 45. This syndrome comprises chronic swelling of the face, peripheral facial palsy, which may be bilateral and which may tend to relapse, and furrowed tongue. In all the patients the disease had its onset with facial palsy before the eighteenth year. In only 1 patient did the swelling of the face occur at the same

time as the facial palsy; in the remaining 4 the paresis appeared from ten to nineteen years before the face became swollen. Some of the patients observed that the swelling began after they had been exposed to cold. In 3 of the patients the swelling was localized to the upper lip, in 2 to both the upper and the lower lip. Both clinically and pathologic-anatomically the facial palsy showed close correspondence to Bell's palsy. In 2 of the patients with bilateral palsy decompression of the facial nerve according to the Ballance-Duel method was done. While in the first patient nothing macroscopically abnormal could be demonstrated in the bone or the nerve on one side, extensive changes both of the mastoid process and the facial nerve were found on the other side. In the other patient there were no abnormal macroscopic findings in the cells of the mastoid process, the canal of the facial nerve or the nerve. During the chronic stage the swelling of the face is due to chronic edema which has all the characteristic features of angioneurotic edema. The facial palsy and the swelling of the face occur within the parts innervated by the facial nerve; it is suggested that in these patients this nerve, besides supplying the voluntary facial muscles with motor fibers, also conducts vasomotor fibers. Decreased function of the former results in facial palsy, whereas disturbance of the innervation of the latter causes neurotrophic facial edema.

Malaria in United States in 1945.—The report by Faust and his associates constitutes the sixteenth consecutive annual report to the National Malaria Society on the status of malaria in the United States. Practically all the reported military malaria was acquired overseas, and much of this is now widely distributed throughout the country as relapsing vivax infection in veterans who have been discharged from service. Malaria mortality in the civilian population continues to show a satisfactory decline. Within a decade it has been reduced approximately nine tenths. Yet there are areas of hyperendemicity remaining in the Southeastern states, in the Mississippi Valley, in eastern Oklahoma and Texas, and in the lower part of the Rio Grande Valley. Most reporting of malaria cases is still inadequate. Certain states, notably those in New England, New York, Ohio and Minnesota, all of which are regarded as essentially nonmalarious, now have widely disseminated cases of malaria in military or veteran personnel. Malaria in veterans in California is also considerable in volume. This may provide a means of reestablishing malaria in areas which have been essentially free of malaria for many years.

Carcinoma Causing Laryngeal Paralysis.—Hassin reports 1 case of bilateral paralysis of the recurrent laryngeal nerve caused by a large carcinoma in the upper third of the esophagus pressing on the trachea and also on the recurrent laryngeal nerves in a man aged 69. The patient became suddenly hoarse and experienced sharp shooting pains in the right side of the head. He died eleven weeks after the onset of the complaints. Necropsy revealed invasion of the muscle tissue by cancer cells, resulting in a variety of changes in the muscle fibers, namely, swelling, fragmentation, loss of striations, liquefaction, fibrillary disruption, degeneration and necrosis. No other pathologic condition of muscle exhibits such a wealth and combination of changes as demonstrated in a muscle invaded by carcinoma. Changes in the muscles and not in the nerves may have been the real cause of the paralysis. The degenerative changes exhibited by some muscle fibers were similar to those seen in progressive muscular atrophy and, like the other changes, are to be considered of toxic and not mechanical origin. Cancer of muscle fibers differs from that of nerve fibers in involving the parenchyma; in nerve fibers the cancer cells are confined to their mesodermal sheaths.

Sturge-Weber-Dimitri's Disease.—Lichtenstein and Rosenberg report 1 case of an abortive form of Sturge-Weber-Dimitri's disease (nevoid amentia), in which superficial heman-

giomatous lesions were not demonstrable in a girl aged 15, who was classified as an idiot at the age of 7 years and who died from bacillary dysentery. The anatomic basis for Sturge-Weber-Dimitri's disease is hemangiomatous mesenchymal dysplasia in the cephalic region, the lesions being predominantly in the mesenchymal layer bordering on the ectoderm, namely, the subcutis, the submucosa of the mouth, nose and throat; the choroid coat of the eye, and the leptomeninges. In the authors' case necropsy revealed that the hemangiomatous lesions in the right occipital lobe were nests of telangiectatic veins which were engorged with blood, being limited to the overlying leptomeninges. The engorged telangiectatic veins played a part in producing venous and capillary stasis in the underlying cerebral cortex. This disturbance in circulation resulted in the depositions of concretions, which replaced large portions of the parenchyma. The concretions are generally rich in calcium or calcium admixed with iron, but in this case calcium was not found, the changes being exclusively in the nature of ferrugination rather than calcification. The concretions appeared histologically as isolated spherules, pericapillary sheaths and incrustated nerve cells. The sclerosis of the affected cerebral convolutions consisted of concretions and a diffuse increase in fibrillary glia, the latter being reactive to the concretions and secondary to the disappearance of nerve cells and the secondary degeneration of nerve fibers. These concretions appear in the roentgenogram as double contour lines outlining the cerebral convolutions. These double contour shadows seen in roentgenograms of the skull in cases of Sturge-Weber-Dimitri's disease are not specific for the disease and have been described in other disorders in which partial interference with the blood supply of the affected convolutions has occurred.

Forms of Iron in Enriched Bread.—The biologic availability of the iron in ferrous sulfate and in ferric orthophosphate has been compared on the basis of hemoglobin regeneration in rats made anemic by iron deficiency. Comparison was made also with ferric chloride. The iron compounds were fed in the form of enriched breads, and multiple levels of enrichment with iron were used to permit comparison of dosage response curves. Under the conditions of these experiments Blumberg and Arnold found that the iron in ferrous sulfate was four to five times as available as that in ferric orthophosphate when both compounds were tested at four widely spaced levels. When compared at two levels, the iron in ferric chloride was equal in biologic availability to that in the highly effective ferrous sulfate or four to five times as available as the iron in ferric orthophos-

phate. The authors stress the desirability of using highly assimilable forms of iron in the enrichment of flour and bread, so that the consumer may secure the full benefit of the enrichment program.

Pulmonary Function After Pneumonectomy.—Birath and his associates point out that pneumonectomies and lobectomies raise the question of whether the remaining lung tissue can carry on the respiratory function. The authors studied 12 patients who had undergone pneumonectomy and 14 patients who had undergone lobectomy for from two to thirteen years after the operation. They found that after pneumonectomy there is somewhat less reduction in total lung volume than the corresponding loss of parenchyma. In the position of maximum inspiration the remaining lung tissue (probably also in the lobectomy cases) is therefore exposed to increased distention. The distention of the lung tissue is approximately 50 per cent greater after pneumonectomy than has previously been calculated. The gaseous elements of the blood in the state of rest as a rule do not exhibit changes. After pneumonectomy and lobectomy, dyspnea is generally stationary and not progressive. After the postoperative period, it steadily diminishes. In many instances it is surprising how little the patient is troubled by it. Twenty-three of the 26 patients had full working capacity. If emphysema develops in the course of years, it generally remains within moderate limits and does not greatly encroach on respiratory function.

Tuberculous Tracheobronchitis.—Judd says that the routine endoscopic examination of all patients who are under consideration for major surgical collapse therapy for pulmonary tuberculosis has made it possible to accumulate much information regarding tuberculous endobronchitis and tracheitis. Among the facts that have been brought to attention are the progressive nature of the changes that culminate in a strangulating stenosis and the value of treatment. Observations were made in 500 cases. The majority of patients revealed some inflammatory reaction suggesting that the severer conditions have their origin in this inflammatory process, which may end in acute stenosis or total occlusion of the airway. The fact that every tuberculous patient does not suffer such a strangulating stenosis is proof that natural resistance interrupts this chain of events in the majority of cases. In addition, bronchoscopic management will interrupt many more. The ultimate number of patients in whom strangulating stenosis develops is small. Endoscopic methods can relieve and "cure" this type of lesion in many cases. Silver nitrate in from 5 to 30 per cent solution is easily applied to ulcerating and granulomatous areas. However, in some patients the application is followed by increase in tissue edema and inflammatory change. Fairly satisfactory results can be obtained by aspirating secretions, removing granulations with the gauze applicator and applying a soothing application, such as cajeput oil ("gomenol") or monochlorophenol in mineral oil. Only endoscopic examination will provide information about endotracheobronchial conditions. The author thinks that in time all patients with advanced tuberculosis will be bronchoscoped prior to the institution of collapse therapy.

Impotence Following Trauma to Corpora Cavernosa Relieved by Cartilage Grafts: Case Report. A. A. Solomon and C. I. Karleen.—p. 289.

"Mapharsen" in Reiter's Disease.—Khoury points out that Reiter's syndrome has a basic triad of bacterial urethritis, conjunctivitis and arthritis. The general belief is that it is one of the many virus infections. Cases reported in the literature generally had a protracted course, but this is not an invariable observation, inasmuch as at least 1 of the 2 cases reported here was benign and cleared in a comparatively short time. The second case may be classed as moderately severe. However, it did cause protracted disability. Large doses of oxophenarsine hydrochloride ("mapharsen"), which were started four months after onset of the urethritis, caused such a rapid and dramatic response that the possibility of a coincidental spontaneous regression cannot be rationally entertained. The author thinks that in future cases of this syndrome this form of therapy should have a trial. "Mapharsen" was given in two injections a week for three weeks, then one injection a week for four weeks. The dose was 0.06 Gm. administered by intravenous injection.

Monocytic Leukemia Appearing as Prostatism.—Lubin and his associates report the history of a man, aged 56, who was hospitalized with symptoms of prostatism. A persistent elevation of temperature and the abnormal blood picture prompted hematologic consultation, which resulted in a diagnosis of subacute monocytic leukemia. This is the second report of a case of monocytic leukemia in which the presenting symptoms were those of prostatic urinary obstruction. The repeated episodes of complete urinary retention can be explained on the basis of recurrent exacerbations of edema of the prostate secondary to the leukemic infiltration. The authors think that if transurethral electroresection is impractical in such cases, alleviation of the obstructive symptoms may be obtained by cystostomy.

Glandular Cancer of Urinary Tract.—Kittredge and his co-workers report 4 cases of glandular carcinoma of the urinary tract, which illustrate the difficulty of determining whether an adenocarcinoma is primary or secondary in this location. In 1 case the tumor of the bladder was probably metastatic from a carcinoma of the colon. In 2 cases the adenocarcinoma probably arose from plaques of urinary tract epithelium which had undergone metaplasia to the secretory type. In 1 case metaplasia of the epithelium to the secretory type evidently occurred in an infiltrating transitional cell carcinoma.

Acute Benadryl Poisoning. T. H. Duerfeldt.—p. 781.

Acute "Benadryl" Poisoning.—Duerfeldt describes the case of a girl 3 years of age, who swallowed approximately fourteen to sixteen capsules (700 to 800 mg.) of diphenhydramine hydrochloride ("benadryl hydrochloride"). The dose taken orally by this girl was 50 to 60 mg. per kilogram of body weight. The symptoms paralleled manifestations of a toxic dose in laboratory animals. At first the child walked with ataxic movements and

had twitching of the face and blurred speech. Suddenly she had generalized convulsive movements, stiffened out for a few seconds and then grew limp and gray and stopped breathing. With artificial respiration her color slowly returned, the muscular twitchings of the face appearing before normal respiratory movements began. Respiratory collapse occurred four times in less than four hours. The convulsions were finally brought under control with rectal administration of ether. The ataxia gradually decreased and disappeared after four days. Repeated examinations during the following months did not reveal evidence of damage to the brain.

Homologous Skin Grafting with Identical Twin as Donor.—Converse and Duchet point out that under the present status of knowledge it is impossible to assure homologous skin transplantation between individual human beings of ordinary genetic diversity. They describe the successful grafting of homologous skin in a case in which the patient's identical twin served as donor. The homografts were used to complete the covering of an area of full thickness skin loss following a war burn. The behavior of the homografts did not differ in any way from that of previously applied autografts. This case confirms previous reports on the success of skin grafting between identical twins.

Malignant Tumors of Small Intestine.—Doub says that although malignant tumors occur less frequently in the small intestine than in other parts of the gastrointestinal tract they are no longer considered as rare as they were in the past. In a review of observations in 52 cases he stresses that the highest percentage of malignant neoplasms of the small bowel are adenocarcinomas. Lymphosarcomas are second in numerical order and carcinoid tumors a poor third. Grossly, the tumors are of two types: constricting and fungating, or polypoid. The constricting type produces mechanical obstruction by narrowing the intestinal lumen; in the polypoid type obstruction is due to the bulk of the

tumor or to intussusception. The clinical picture is usually one of a progressive loss of weight and strength and varying degrees of anemia. Pain is a prominent symptom. A change of bowel habit is usually present, and this may progress to an acute obstruction for which the patient seeks relief. A palpable tumor is an important and significant finding. Distention is often present. Unusual peristaltic activity is common. The roentgen picture may reveal an area of narrowing of the lumen of the bowel and dilatation proximal to it. Marginal or central filling defects may also be present, with obliteration of the mucosal markings in the involved area. Varying degrees of obstruction of the duodenum and stomach are commonly found associated with duodenal tumors. In the periampullary type jaundice, often of an intermittent character, is a prominent feature. The symptoms and roentgenologic signs of jejunal and ileal tumors are similar. In these areas the clinical syndrome is usually that of obstruction. The symptoms may be acute and constitutional in the case of intussusception or gradual in the case of a slow growing tumor. Loss of weight and strength combined with anemia and a palpable abdominal tumor are suggestive signs.

Calcium Penicillin in Syphilis.—Koch treated 279 patients with early syphilis by daily intramuscular injections of calcium penicillin in oil and 4.8 per cent beeswax for ten days at the San Francisco City Clinic during the period August 1945 to April 1947. Treatment consisted of two administrations of 150,000 units (0.5 cc.) of penicillin, one in the morning and one in the evening, making a total of 3,000,000 units of the drug for the entire treatment schedule. Of the 279 patients treated, 238 (85.3 per cent), 169 men and 69 women, completed the course of treatment. Thirty-five failed to complete the course for various reasons, and 6 of the patients are still under treatment. Eighteen patients displayed reactions, but in only 3 patients were these sufficiently severe to necessitate discontinuance of penicillin treatment. Of the 238 patients, 140 had primary syphilis and 98 had secondary syphilis. Sixty-eight of the 140 and 26 of the 98 attained seronegativity and were followed for periods varying from less than three months to more than eighteen months. One hundred and eighty-one of the 238 patients were followed from one to eighteen months. The failure rate of these cases was 10.5 per cent, and the failure rate based on 136 cases followed from three to eighteen months was 14 per cent. A combination of this method of treatment with arsenicals and bismuth compounds has been recommended for use in the physician's office.

Pemphigus Vulgaris.—Barnard reports 1 case of pemphigus vulgaris in a man aged 77; estrapenia, i. e., diminution in blood cholinesterase, and erythrophthisis were demonstrated at necropsy. It is suggested that the manifestations of pemphigus may be due to erythroid marrow depression, failure of cholinesterase synthesis and cholinergic intoxication. Fatal pemphigus may be classified along with the acute forms of malignant leukoses as an atopic exudative shock state. The bone marrow must be regarded as the crucial shock organ. On the basis of its presumed pathogenesis, blood transfusion appears to be the rational keystone in the treatment of pemphigus. Penicillin and arsenic therapy would appear to be useful. Radiation therapy may give the death blow to an erythroid marrow struggling for existence; this treatment is interdicted in all estrapenic conditions and would appear to be contraindicated in pemphigus.

Absorption Collapse in Tuberculosis.—Graham and Hutchison show that drainage from the primary focus of tuberculosis takes place via the peribronchial lymphatics to the regional lymph nodes. Tuberculin skin tests are positive. A follow-up of positive reactors has revealed a varied course. By far the greatest number proceed to healing. Certain phenomena occasionally appear which are regarded as due to allergy, namely, erythema nodosum and phlyctenular conjunctivitis. Bronchogenic spread producing tuberculous bronchopneumonia and hematogenous spread producing miliary tuberculosis and tuberculous meningitis with rare exceptions end in death. The authors discuss the condition accompanied by extensive radiologic changes in the lungs which has been designated as epituberculosis. Various explanations have been attempted for this condition. The authors incline to the one which assumes that such lesions are due to the pressure of the tuberculous regional lymph nodes on the adjacent bronchi; the pressure produces various degrees of occlusion, which in turn leads to collapse of the corresponding lobe or sector (absorption collapse). Evidence in favor of this theory is presented. A number of illustrative case histories are given, and the authors stress that absorption collapse due to bronchial occlusion is of common occurrence in primary tuberculous infection in children. In some cases of incomplete bronchial occlusion, obstructive emphysema may result. The term "epituberculosis" applied to this condition is a misnomer, and the suggestion that the shadow seen in the radiograph indicates a perifocal reaction of an allergic nature is not justified. It might be suggested that in a child in whom a bronchus is occluded by a mass of tuberculous granulation tissue containing virulent tubercle bacilli bronchoscopy is contraindicated, and that the removal of the tuberculous granulation tissue via the bronchoscope might be followed by a rapid spread of the infection and the death of the patient. Such does not seem to be the case. Failure to bring about expansion of the collapsed lung may result in the development of bronchiectasis. Further observations on the final results obtained by bronchoscopy and removal of the obstruction compared with results in those not so treated are urgently required.

Tomography in Tuberculosis of Spine.—According to Wood and Wilkinson, although ordinary anteroposterior and lateral radiographs are useful in defining the extent and progress of tuberculosis of the spine, there are situations in which such roentgen examination is made difficult by the intervention of structures that overlap and obscure the part to be viewed. Tomography is of special value in such regions. It is also of use in obtaining better definition of tuberculous foci in the spine. In 1 of the patients studied by the authors tomography made possible the accurate demonstration of the site of origin of the tuberculous sinus and the operative approach. In tuberculous paraplegia it is difficult to assess the integrity of the spinal

canal by the ordinary anteroposterior and lateral films without the aid of tomographs. The authors cite cases and reproduce tomographs to show the value of tomography in the presence of tuberculous disease in the upper cervical, cervicodorsal and lumbosacral regions. They discuss tomography in relation to tuberculous paraplegia.

Penicillin in Neurosyphilis.—Worster-Drought employed sodium penicillin in aqueous solution. He thinks that a total dosage of at least 3,000,000 units of the drug should be given to patients with neurosyphilis and that in parenchymatous neurosyphilis the total dosage should reach 4,000,000 to 5,000,000 units. Intramuscular injection is the best method of administering penicillin. The intravenous route (either by continuous drip or by repeated single injections) has little to commend it. There is no evidence that the intrathecal administration of penicillin is of greater therapeutic value. Because of the reactions and the various additional risks, intrathecal injection of penicillin is best avoided in most cases of neurosyphilis. Owing to the risk of possible Herxheimer-Jarisch reactions following the first doses of penicillin, all patients with neurosyphilis should receive an initial series of injections of a bismuth compound. In meningeovascular neurosyphilis the course of penicillin should be followed by arsenic and bismuth therapy. General paresis is best treated with an initial course of 4,000,000 to 5,000,000 units followed by full malarial or fever therapy (10 to 12 malarial rigors). The usual courses of arsenic and bismuth are advisable until the serologic reactions become negative. In cases of dementia paralytica (and taboparesis) in which malarial or fever therapy is contraindicated by reason of cardiovascular disease, one must rely on penicillin alone. Some improvement, but not cure, can be expected. Tabes dorsalis is best treated first with penicillin and then with arsenicals and bismuth preparations. In primary optic atrophy of syphilitic origin treatment should consist of an initial course of 4,000,000 to 5,000,000 units of penicillin followed by malarial therapy and afterward arsenic and bismuth therapy. Observation of patients must extend to five years or longer before success can be claimed for any treatment.

Labyrinthine Fenestration.—Hutchinson favors the one stage posterosuperior operation under general anesthesia with gas-oxygen-trichloroethylene and with adoption of the operating microscope. Free and tangential access is provided by the posterosuperior approach in contrast to the vertical and restricted access afforded by Lempert's transmeatal approach. The actual fenestration itself is performed in a continuous controllable stream of isotonic sodium chloride solution to which a few drops of epinephrine have been added. The most suitable patient for operation is the young, intelligent adult between the ages of 20 and 30, with audiograms showing a flat conduction curve of more than 30 decibels and more or less good bone conduction hearing. Systematic treatment should be practiced both before and after surgical intervention. Vertigo may or may not occur;

its duration is usually short and the response to treatment with phenobarbital is satisfactory. The patient gets up about the sixth day and leaves the hospital about the twelfth to fourteenth day on the average. At the first dressing on the eighth post-operative day hearing may be as poor or poorer than it was before operation; about the end of another week it usually begins to improve, and it reaches its peak in two to six months. There is a fifty-fifty chance of a 25 to 35 decibel improvement in hearing, and such improvement if retained for two years will be permanent. The careful selection of cases, the thorough preliminary drilling of the theater team, the orthopedic preparation of the patient, a completely adequate armamentarium, the most rigidly aseptic operative and postoperative technic and meticulous attention to detail at operation are all factors of importance if success is to be attained. Since closure of the fenestration as the result of osteogenesis may occur up to two years from the date of operation in some 10 per cent of cases regardless of what steps are taken to prevent it, this period of time should be allowed to elapse in every instance before attempting to assess the permanent degree of success.

 Rhesus Antigen C^w Causing Hemolytic Disease of Newborn. Sylvia D. Lawler and J. J. van Loghem.—p. 545.

Beta Chloroethylamine Hydrochlorides in Leukemia.—Wilkinson and Fletcher describe the results of treatment with intravenous halogenated alkylamine (nitrogen mustard) in 18 cases of chronic myeloid and lymphatic leukemia, Hodgkin's disease and polycythemia vera. Diagnosis was confirmed by biopsy of lymph nodes or of sternal marrow. The most beneficial effects were observed in chronic myeloid leukemia, though dramatic improvement also occurred in Hodgkin's disease.

There was considerable variation in the response to treatment in individual cases in all groups, but the least satisfactory results were obtained in chronic lymphatic leukemia. A dosage of 0.1 to 0.2 mg. per kilogram of body weight was adopted, and tris (beta-chloroethyl)amine hydrochloride was the compound of choice. Undesirable toxic effects were avoided by hematologic control and a safe technic of administration. The two alkylamines do not appear to cure leukemia or the other conditions mentioned, but in some cases they give relief by reducing the total white blood cell count, with a resultant improvement in the anemia. In other cases embarrassing enlargements of the lymph nodes, liver and spleen disappear, leading to an increased feeling of well-being. Improvement is seldom maintained, and the patient's response to this treatment appears to diminish after repeated injections. It may be an advantage to use some form of combined therapy or to give different preparations of varying activity on the hemopoietic organs at certain stages of the disease.

Rhesus Antigen C^w and Hemolytic Disease of the Newborn.—Lawler and van Loghem point out that a rare Rh antigen, C^w was described by Callender and Race in 1946. A patient responded to blood transfusions by making a succession of "new" antibodies. One of these antibodies was called anti-C^w. Two of the donors were eventually recognized as being C^wDe/CDe. C^w is a form of antigen alternative to C or c; it occurs in the bloods of about 2.5 per cent of English persons. The authors report a second example of anti-C^w. In this case the Rh antibody, anti-C^w, resulted from immunization by pregnancy and caused hemolytic disease of the newborn. The mother had never received a transfusion, but her first child had been jaundiced for a month. It recovered, however. A second infant died on the third day from icterus gravis. A year later a macerated fetus was stillborn. This was followed by a miscarriage during the fourth month. Another infant died from icterus gravis neonatorum, and the last infant, born in June 1947, died of erythroblastosis fetalis. The mother's serum, taken after the birth of the last child, agglutinated the cells of both father and baby. The blood groups of the family at first appeared to be compatible in all respects. Nevertheless the presence of the antibody and the history, which was typical of hemolytic disease, strongly suggested that Rh incompatibility must be present. The samples of blood from both mother and father were then tested against the serum of the Oxford patient containing the original anti-C^w agglutinin. The antigen C^w was found in the father's blood but not in the mother's; thus an Rh antigen incompatibility was disclosed. The antibody in the mother's serum was then proved to be anti-C^w by testing its reactions with a panel of cells of laboratory workers previously tested with the Oxford serum.

Management of Hand Injuries.—Woodland pleads for recognition of the seriousness of injuries to the hand and digits. Mangled fingers and hands result in more permanent deformities than major fractures of the large bones, and injuries to the hand and fingers result in far greater economic loss to the patient. The annual report of the Workers' Compensation Commission of New South Wales for the year 1944-1945 shows that there were 86,906 cases of compensated injury. Of these injuries, 26,862 (31 per cent) involved either the digits or the hand. After analyzing the location and nature of hand injuries, the author discusses the 2 commonest injuries of bones and joints of digits, fracture of the index finger and sprains of the thumb. Sepsis of the hand and treatment of stiff fingers is also discussed. He stresses that in addition to the uniform adoption of the improved technic in the treatment of fracture of bone and joints of the hands, more hospital beds and facilities for remedial occupational therapy in workshops are necessary before the disability rate will be lowered.

Clinical Significance of Study of Supraclavicular Lymph Nodes in Cancer. E. Jakobson.—p. 75.
Two Cases of Primary Suppurative Psoas Myositis. E. E. Vuori.—p. 87.

Acute Hepatitis.—Bergenfeldt operated on 7 patients with acute hepatitis, 4 men and 3 women between the ages of 42 and 58, in whom jaundice was refractory to medical treatment. Surgical intervention consisted of perfusion of the biliary passages with contrast medium for cholangiography supplemented by perfusion with isotonic sodium chloride solution in certain cases. The jaundice disappeared rapidly and the patients recovered. Relapses did not occur, and all the patients were in good health on follow-up examination up to three years and nine months after the operation. It is suggested that a relative obstruction was caused in the lower part of the common bile duct by an accumulation of tenacious mucus and cohesion of the mucosal surfaces. The hepatitis is accentuated by the impeded flow of bile, which is under subnormal pressure due to the hepatitis; the pressure drops still further, and a vicious circle develops. This is broken by the surgical intervention. The relative obstruction of the common bile duct must be considered not as the cause but as the result and complication of the hepatitis. The biliary passages of a patient who died of acute hepatitis were perfused during necropsy; a firm plug of mucus was expelled from the duodenal papilla, followed by large quantities of mucus. Similar observations were made in the post-mortem of a pig which had died of acute hepatitis. The results of the serum citric acid test and the serum phosphatase test also support the author's concept. Surgical treatment is recommended in doubtful cases in which differential diagnosis of hepatitis from obstructive icterus may be difficult and in certain cases of hepatitis in which severe icterus has persisted for weeks or months. Surgical intervention should consist in cleansing the biliary passages; this may be achieved by perfusion.

Postoperative "Dicumarol" Prophylaxis.—Borgström divided 1,831 patients, 900 men and 931 women between the ages of 25 and 85 years, who were operated on at the surgical clinic in Lund during 1946, into two groups. Nine hundred and forty patients with odd numbers were to be given "dicumarol" therapy provided that this was not contraindicated, while 891 patients with even numbers were to serve as controls, being treated only by early ambulation. Only 701 (337 men and 364 women) of the 940 patients were treated with "dicumarol" while 1,130 (563 men and 567 women) were not. These two groups were comparable as to age, operative intervention, time in bed postoperatively and weight. The two latter factors were examined only in patients operated on for appendicitis, hernia and cholelithiasis. Patients with transvesical prostatectomy have not been included because of their greater age (68 at an average) and the high incidence of thromboembolism among these patients. By dividing the material according to sex, no difference was observed in the incidence of thromboembolism among the men treated with "dicumarol" and those of the control group, while the incidence of thromboembolism was definitely lower among the women treated with "dicumarol" and those not so treated. This applies to the statistics based on the whole group of 940 patients compared to those based on the 701 patients. In addition it was demonstrated that the risk of bleeding associated with postoperative "dicumarol" therapy is insignificant and that the incidence of fatal pulmonary embolism has been definitely reduced. Postoperative "dicumarol" prophylaxis is suggested for women at postoperative early rising, while for men this prophylaxis seems to be without demonstrated value. A possible decrease in the incidence of fatal pulmonary embolism should, however, be emphasized.

Appendicitis.—Ekström reports 2,349 cases of appendicitis in 1,654 men and 695 women. The mortality for the whole group was 0.38 per cent $\pm$ 0.01 per cent. Sixteen hundred and four of these patients were operated on for acute appendicitis. The percentage of perforations (7.4) was unusually low and may be related to the fact that the patients came from a large urban population and had been admitted to the hospital early after the onset. This may also account for the low mortality of 0.44 per cent $\pm$ 0.16 per cent in this group. Postoperative chemotherapy may have played an additional part. Temperature, blood sedimentation rate and white blood cell count were of secondary aid to diagnosis. Nineteen of 33 patients with appendical abscess were operated on; treatment consisted of drainage in 17 and of appendectomy in 2. Conservative treatment was practiced in the others, for whom an appendectomy was advised at a later time. Death resulted from cardiac decompensation in 1 patient aged 73. Four hundred and forty-nine patients with noninflamed appendixes were operated on because of diagnosis of acute appendicitis. The commonest cause of the erroneous diagnosis was intestinal infection of various types. Women were in a significant majority (68 per cent), perhaps because intestinal disturbances are more frequent among women. One death occurred in this group, but it was not related to the operation. Two hundred and sixty-three patients with chronic appendicitis underwent operative intervention. Four-fifths of the patients were women. In 20 per cent the appendix was normal. Follow-up studies showed that 187 (83 per cent) were completely free from all abdominal symptoms. The best results were obtained in the cases of active chronic inflammation of the appendix and in cases with a typical history; in this group no deaths occurred among those who submitted to operation.

Vitamin B₁ in Postdiphtheritic Polyneuritis.—Bøe points out that since vitamin B₁ has given excellent results in the polyneuritis of beriberi it has also been tried in other forms of polyneuritis, although in these the indications for its use are not so definite. In the course of an epidemic of diphtheria with many toxic cases, an investigation was undertaken to ascertain the extent to which thiamine can prevent polyneuritis and whether large doses of this vitamin, given when polyneuritis had appeared, could have any influence on the course of the disease. Of 80 patients with toxic diphtheria every other one was treated with thiamine, the alternate patients serving as controls. The patients receiving vitamin B₁ were given 3 mg. daily by mouth, and as soon as signs of polyneuritis appeared they received a supplementary dose of 25 mg. of vitamin B₁ given daily by injection for five days. After ten days without therapy a new series of five injections of 25 mg. each was given. These injections for five days with ten day intervals were repeated as long as the patient remained in hospital. With this dosage vitamin B₁ appeared to have no effect whatever on the polyneuritis. Complications appeared just as often, just as early, and lasted just as long in the vitamin treated group as in the control group. There would seem to be little evidence in support of the employment of vitamin B₁ in postdiphtheritic polyneuritis.

"Diodrast" Clearance and Tubular Excretory Capacity.—Josephson reviews several technics of determination of renal "diodrast" clearance and of renal tubular excretory capacity for "diodrast" (iodopyracet injection U. S. P.), pointing out their shortcomings. Since 1942 he used a method, which he found comparatively convenient and reliable, consisting of a combina-

tion of two injections for the determination of renal plasma flow and tubular excretory capacity. The "diodrast" clearance is studied after one single intragluteal injection of the contrast medium and the tubular excretion capacity after one subsequent single intravenous injection.

*Tuberculosis of Thyroid: 2 Cases. G. Coggi.—p. 223.

Tuberculosis of Thyroid.—The condition is rare. The subjects of Goggi's report are 2 women aged 26 and 58 years, respectively. The youngest patient had healed pulmonary tuberculosis. A cold abscess developed within a thyroid adenoma secondary to healed pulmonary disease. Treatment consisted of partial thyroidectomy. The older patient was suffering with tuberculosis of the tibia and of the tarsal bones. Thyroidectomy was contraindicated because of the acute degree of infiltration of the perithyroid tissue. Treatment consisted of transsection of the thyroid tumor and use of filiform drains for two months. In both cases the diagnosis of tuberculosis of the thyroid was verified by histologic studies of the removed tissue and biologic tests.

Role of Physical Therapy in Infections of Hand. P. Bauwens.—p. 2275.

*Antithyroid Action of Estrone. J. Lederer.—p. 2290.

Antithyroid Action of Estrone.—According to Lederer, goiter is much more frequent in women than in men, the ratio being about 9:1. Numerous studies have revealed a close functional relation between thyroid and ovary. Goiter and hyperthyroidism often occur following decisive changes in the genital sphere of women, at the time of puberty, pregnancy, menopause and castration. Accordingly, it was decided to try estrone in the treatment of those cases of hyperthyroidism that were associated with suppression of the ovarian function. The author presents the histories of 4 women with exophthalmic goiter in whom large doses of estrone were given. In 2 of them the hyperthyroid condition developed following castration and in 2 others during the menopause. In those who had undergone castration, 25 mg. of estradiol benzoate was injected during the first week; during the succeeding two weeks 20 mg., and after that 15, 10 and 5 mg. of the drug were injected weekly. The women of menopausal age at first were given two weekly intramuscular injections of 5 mg. of estradiol benzoate; then this dose was given once every week and finally once in two weeks. As a result of this treatment the patients improved rapidly. They gained in weight, the basal metabolic rate and the pulse rate decreased, the goiter diminished considerably and the exophthalmos regressed.

*Successful Treatment of Severe Air Embolism by Puncture of Ventricle of Heart. W. Lembcke.—p. 31.

Severe Air Embolism.—Lembcke reports 1 case of severe air embolism which occurred during skin suture after strumectomy in a woman aged 33. The clinical aspect resembled that of asphyxia. The patient was unconscious, the pupils did not react, the reflexes were absent. Peroral intubation demonstrated that the air passages were free. Circulatory and respiratory analeptics were ineffective, and only temporary improvement in the cadaverous discoloration of the skin resulted from the administration of oxygen. The presence of bloody foam was revealed by puncture of the right ventricle by means of a thin cannula. The foam was sucked off with an airtight syringe. The puncture was repeated three times. The first punctures resulted in only temporary improvement of circulation and respiration, and the patient remained unconscious. The third time the cannula was left in the right ventricle for ten minutes and air and foam

were sucked off repeatedly. The pupils began to react, the pulse became less rapid, the cadaverous color of the skin changed to mild cyanosis and consciousness was restored in twenty minutes. It is suggested that the air embolism resulted primarily from disturbance of the air exchange depending on an obstruction of the blood current between the right heart and the capillaries of the lungs. The right ventricle, the pulmonary artery and part of the capillaries of the lung were obstructed by the air that had entered the circulation. Small amounts of blood still reached the lungs, but the blood supply of the various organs was insufficient, thus causing a severe decrease in function. The heart which is filled with air beats "in vain." This combined with the insufficient supply of blood to the heart and the organs would result in the cessation of the circulation. The only effective method of treatment is the removal of the mechanical obstruction of the right heart by sucking off the air. This measure may then be followed by the administration of various analeptics.

Indications, Technique and Results of Penicillin Therapy in Infections of Obstetric Origin. M. Mayer.—p. 105.

Porphyrinuria in Extrauterine Pregnancy.—Neuweiler and Rupp-Haller report that at the Women's Clinic of the University of Bern the porphyrin content of the urine was determined in nearly 400 patients in whom extrauterine pregnancy was present or suspected or who had other disorders in which porphyrin excretion was of interest. Porphyrin was demonstrated by means of the rapid method of Brugsch, which is based on the red fluorescence of the porphyrins in ultraviolet light. In two thirds of 122 patients with extrauterine pregnancy the porphyrin excretion in the urine was noticeably or considerably increased. In nearly a fifth the porphyrin reaction was weak, and in the remaining patients porphyrinuria was absent. Considering separately the various forms of extrauterine pregnancy, the authors found that in case of interrupted extrauterine pregnancy with the formation of hematocele, the incidence of porphyrinuria was somewhat higher; it occurred in 18 of 21 patients. As a rule, the porphyrinuria appeared rapidly, that is, from one to two days after onset of intra-abdominal hemorrhage. The authors found that porphyrinuria was a much more reliable indication of intra-abdominal hemorrhage than the urobilinogenuria. Of 100 women with intrauterine abortion, 28 had a greatly increased and 12 a weak elimination of porphyrin and in the other 60 it was normal. In patients with adnexitis porphyrinuria was positive in 58 per cent and negative in 42 per cent. In patients who had ovarian tumors with torsion of the pedicle and usually with hemorrhagic perfusion, 13 of 17 showed a great increase and 2 a slight increase in urinary porphyrin.

Klinische Wochenschrift, Würzburg

24/25:1-64 (Oct. 1 and Oct. 15) 1946. Partial Index

Physiologic Bases of Mechanics of Heart. H. Reichel.—p. 1.

Carbohydrate Metabolism in Experimental Traumatic Tetanus. H. Staudinger.—p. 16.

*Oral Treatment of Pernicious Anemia with Small Amounts of Liver. F. Bahner.—p. 28.

Enterococcic Pneumonia.—Lüdin reports 7 cases of enterococcic pneumonia in 4 women and 3 men between the ages of 25 and 63. The patients had severe bronchopneumonia which was resistant to sulfonamide compounds. Bacteriologic studies revealed enterococci in the sputum; pneumococci were absent. In 1 patient a drop in temperature, rapid improvement in the general condition and lowered pulse rate followed the administration of antienterococcus monovalent horse serum. Fifteen

cubic centimeters of the serum were given by intramuscular route and 10 cc. intravenously. A second intravenous injection of 20 cc. was given the next day. Enterococci may be considered as an etiologic factor in pneumonia even though they have been found in the oral and pharyngeal cavities and in about 20 per cent of sputums of normal persons and have been described as nonpathogenic for man.

Liver Treatment of Pernicious Anemia.—Bahner treated 15 patients with pernicious anemia by oral administration of small amounts of predigested beef liver. The initial daily dose consisted of 20 Gm. of cut liver mixed with acid gastric juice. An approximate ten week course of treatment was required for restoring the blood picture to normal. Twenty grams of predigested liver twice a week were required as a maintenance dose in 7 patients, 20 Gm. of predigested liver three times a week in 2 patients and 20 Gm. of predigested liver six times a week in 6 patients. Additional treatment consisted of 1 teaspoon of hydrochloric acid in 1 glass of water at each meal. In recent cases of pernicious anemia routine treatment has now been instituted with daily doses of 40 Gm. of predigested liver to be continued until the blood picture has been restored to normal, after which a maintenance dose of 20 Gm. of predigested liver several times a week may be sufficient. To cure pernicious anemia the maintenance dose should be increased to 40 Gm. daily. There were no failures. The advantage of beef liver administered by mouth, as compared to liver extract administered intravenously, consists in the richer content of vitamins and highly potent proteins. This is particularly important in countries where nutrition is precarious, because administration of antipernicious substance leads to renovation of blood only provided that the erythropoietic apparatus has enough food proteins at its disposal. By the method described pernicious anemia can be cured in ambulant patients independently of liver extract preparations. Combined parenteral and oral treatment is indicated if there are only limited quantities of liver extract preparations available or if the available preparations are not adequately effective.

Improved Method of Search for Treponemas in the Dark Field. A. Bijndendijk.—p. 2667.

Necrotic Arteritis Following Sulfonamide Therapy.—Van Rijssel and Meyler report 6 patients in whom necropsy revealed necrotizing arteritis, which was attributed to allergy resulting from medication with sulfonamide compounds. In view of the serious dangers resulting from sensitization, the authors issue a warning against the use of sulfonamide drugs in cases in which they are not strictly indicated. The authors cite the case of a patient with carcinoma, who was given large doses of sulfadiazine in treatment of pneumonia. He died, and necropsy revealed arteritis in spleen, liver and lungs. The renal vessels were not involved, and the clinical history indicates that the renal function had been unimpaired to the end. This indicates that arteritis may develop in sulfonamide therapy even when the function remains normal.

- *Chronic Superficial Punctate Keratitis by Onchocerca Volvulus. M. Appelmans.—p. 129.
Action of Testosterone Preparations on Intraocular Pressure. Magda Radnót.—p. 168.

Chronic Superficial Punctate Keratitis by Onchocerca Volvulus.—According to Appelmans the chronic form of punctate keratitis prevails in endemic form in central America and in tropical Africa. Its etiologic basis is variable. They report 2 cases in which chronic superficial punctate keratitis was caused by *Onchocerca volvulus*. The patients were Europeans recently returned from the Belgian Congo. A definite diagnosis of onchocerciasis requires the biomicroscopic demonstration of mobile larvae. It is not sufficient that a patient with filariasis who has been in the tropics shows chronic superficial punctate

keratitis or uveitis with eosinophilia; there must be proof of the presence of the exact species of the parasites in the eye. The presence of larvae of *Onchocerca volvulus* in the anterior chamber is not sufficient to produce an iritis. Allergic factors also seem to play a part in the origin of keratitis and uveitis. The only treatment known is the extirpation of the filarial nodules. This hinders the increase of embryos and prevents entry of larvae into the eye, as long as the carrier is guarded against new infection. The author recommends an application of 5 per cent mercurous chloride ointment in the conjunctival sac to alleviate keratitis punctata caused by filariasis in those cases which do not exhibit parasitic tumors.

- *Preservation of Solutions of Penicillin and Streptomycin and of Combined Solutions of Penicillin and Streptomycin: Conclusions. G. Ramon and R. Richou.—p. 693.
*Bronchial Syndrome According to Bronchoscopic Observations. A. Soulas.—p. 694.
Considerations on Tracing of Syphilis by Systematic Serologic Examinations (Practical Value of Micromethods). M. Foustier.—p. 695.

Preservation of Solutions of Penicillin and Streptomycin.—Experiments by Ramon and Richou demonstrated that penicillin treated with from 0.03 to 0.05 per cent of the commercial solution of formaldehyde for the solution of penicillin, or treated simultaneously with formaldehyde and warming up to 55 C. (131 F.), will retain its antibiotic properties and will not become contaminated with microbes for more than three months at temperatures of 2 to 4 C. (35.6 to 39.2 F.) and for four weeks at temperatures of 15 to 20 C. (59 to 68 F.). The same applies to solutions of streptomycin for a period of about four months at laboratory temperatures of 13 to 18 C. (55.4 to 64.4 F.) when 0.03 per cent of formaldehyde had been added to the solution of streptomycin. A combined solution of penicillin and streptomycin treated with formaldehyde will remain sterile and stable for a period of time comparable to that recorded for each of these substances in separate solution. The employment particularly of the combined solution will facilitate antibiotic therapy on a broader scale especially against mixed infections caused by bacteria partly resistant either to streptomycin or to penicillin or against infections in which the microbic agent has not been determined by laboratory methods before treatment is instituted. A combined solution of penicillin and streptomycin is indicated for local treatment of convalescents or carriers of diphtheria and for persons suffering from or exposed to whooping cough.

The Bronchial Syndrome.—According to Soulas the anatomophysiological changes of the bronchial tube and of the bronchial wall have a controlling influence on the bronchial syndrome. Changes in the bronchial wall are characterized by edema, and that applies to transitory and superficial lesions resulting in functional disturbances, to organic lesions, such as erosive inflammation or ulceration, and to an involvement extending far below the surface, such as necrosis, stenosis or new growth. Whether superficial or deep, the parietal lesion produces disturbances lessening the secretion of mucus. There is also deficient expulsion of the bronchial secretion, due not only to the deficient vector represented by the cilia and the mucus but also to lessened motility of the wall. This threefold deficiency in the defense power of the bronchus causes not only obstruction but also stagnation and retention. Bronchoscopic treatment should be directed to the relief of the obstruction of the bronchial tree by clearing the bronchi and by restoring their secretory, excretory and motor power. The peribronchial tissue also plays an important part in the bronchial syndrome by representing the junction between the main bronchial tree and the parenchymatous area causing a response in one of the broncho-alveolar sectors. This relationship explains certain factors in extensive or localized pulmonary atelectasis in which the bronchial obstruction appears to be incomplete or there is only mild hypoventilation in spite of apparent complete obstruction. The same concept explains certain types of bronchiectatic suppuration which results from endobronchial and peribronchial lesions. It may also be an aid to understanding the localized so-called atelectatic or emphysematous processes temporarily associated with various bronchopulmonary disorders.

Book Notices

A Textbook of Medicine. Edited by Russell L. Cecil, A.B., M.D., Sc.D., Professor of Clinical Medicine, Cornell University Medical College, New York, with the assistance of Walsh McDermott, M.D., Associate Professor of Medicine, Cornell University Medical College, Associate Editor for Diseases of the Nervous System, Harold G. Wolff, M.D., Associate Professor of Neurology, Cornell University Medical College. Seventh edition. Cloth. Price, \$12. Pp. 1730, with 244 illustrations. W. B. Saunders Company, West Washington Square, Philadelphia 5, 1947.

This latest edition of what has come to be a leading textbook of medicine is some 170 pages longer than the previous edition and has many revisions. Among the new articles in the current volume are many on nutritional disturbances, one on psychosomatic medicine and one on narcolepsy. Because of the deaths of some of the former contributors, new articles have been prepared on conditions caused by viruses, on many infections and on many disturbances of the nervous system. Some colored illustrations have been added to the text. Because of changes in knowledge of the etiology of certain diseases there are transpositions of material. Conspicuous is the resignation of Dr. Foster Kennedy as associate editor for diseases of the nervous system. His place has been taken by Dr. Harold G. Wolff, professor of medicine in charge of nervous diseases in the Cornell University Medical College. Because of the considerable number of specialists who contribute to this book and the careful editing, the volume continues to maintain a place of great importance among books available for teaching the practice of medicine.

Elementary Medical Physics. By Howard O. Stearns, Associate Professor of Physics, Simmons College, Boston. Cloth. Price, \$4.75. Pp. 354, with illustrations. The Macmillan Co., 60 Fifth Ave., New York 11, 1947.

This textbook is written with the laudable idea of correlating the important subject of physics with biologic and medical sciences and of pointing out to the students where and how the laws of physics are applied to apparatus and instruments used in the practice of medicine. The objective of the author is meritorious. Too few textbooks on physics have been written for the premedical student, with the unfortunate result that in general the student has been less interested in physics than in any other basic science.

The book is aimed at the level of an introductory course in college. The author has made an attempt to simplify the mathematical analysis which is so necessary to an understanding of physics.

There are scattered through the book many applications of important laws and physical principles pertaining to biologic or medical sciences. This is an innovation, because many textbooks on physics employ mainly applications bearing on engineering or other technical uses. For example, to illustrate forces the bones and muscles of the body are depicted instead of a bridge or crane.

Colleges and universities training premedical students might well consider use of this textbook. It is recommended as a supplemental textbook for the special classes composed of premedical students only. Teachers of physical therapy and x-ray technicians will find the textbook a useful pedagogic aid.

The Fungi. Volumes I and II. By Frederick A. Wolf and Frederick T. Wolf. In two volumes. Cloth. Price, \$6; \$6.50. Pp. 438, with 153 illustrations; 538, with 82 illustrations. John Wiley & Sons, Inc., 440 Fourth Ave., New York 16; Chapman & Hall, Ltd., 37-39 Essex St., Strand, London, W. C. 2, 1947.

Fungi have received increased attention during recent years because of the important role that they play in many natural processes. These are specific processes such as (1) the production by fungi of penicillin and other antibiotics; (2) the use of fungi in many important fermentations, such as the manufacture of citric, fumaric, itaconic and other acids; (3) the role of fungi in the destruction of many kinds of service materials, including cotton and leather goods, optical instruments and electrical equipment, under tropical conditions, and (4) the causation by fungi of human diseases.

A great need exists for a comprehensive summary of present knowledge of the nature of fungi, their physiology and their

role in natural processes. These two volumes have amply filled this need and serve as an introduction to more specialized fields.

The first volume is devoted to a discussion of isolation, cultivation and classification of fungi and a description of the more important groups.

Each chapter has adequate reference to literature wherein the reader can obtain further information. Each volume has a comprehensive author and subject index.

The chapter on medical mycology in the second volume will be of particular interest to the medical reader. After brief historical survey of the subject, the authors discuss important disease organisms such as *Trichophyta* or ringworm fungi, *Coccidioides immitis*, *Histoplasma capsulatum*, *Aspergillus fumigatus*, *Sporotrichum schenckii*, *Actinomyces bovis* and *Monilia (candida)*.

Other chapters, notably those dealing with the poisonous and edible fungi and fungus-insect interrelationships, also are of definite interest. One would prefer inclusion of two additional chapters, one dealing with the production of antibiotics by fungi, and another on fungistatic and fungicidal agents.

The Principles and Practice of Medicine: Designed for the Use of Practitioners and Students of Medicine. Originally Written by William Osler, M.D., F.R.C.P. By Henry A. Christlan, A.M., M.D., LL.D. Sixteenth edition. Cloth. Price, \$10. Pp. 1539. D. Appleton-Century Co., Inc., 35 W. 32nd St., New York 1; 34 Bedford St., Strand London, W. C. 2, 1947.

Proof that time marches on is apparent in the sixteenth edition of Osler's "Principles and Practice of Medicine." The name Osler has disappeared from the cover, but the title page indicates that this is the book "originally written by William Osler, M.D."

Dr. Christian calls attention in his introduction to many additions that have been made since the last previous edition in 1944. These concern principally the use of the antibiotic and sulfonamide drugs in treatment and new classifications based on advancing knowledge of infections. "Catarrhal jaundice" and "Weil's disease" have been discarded, to be replaced by hepatitis of many varieties.

In this edition also appears a brief history of the Osler textbook of medicine prepared by Dr. James G. Carr of Chicago, with incidentally a facsimile of a note of appreciation written by William Osler in 1892. The present edition is approximately 40 pages longer than the last previous edition—an indication of the new material that has been added.

Stop Annoying Your Children. By W. W. Bauer, M.D., Director, Bureau of Health Education, and Associate Editor of *Hygeia*. Cloth. Price, \$2.75. Pp. 272, with illustrations. Bobbs-Merrill Co., 724-730 N. Meridian St., Indianapolis 7, 1947.

Even if the last chapter in this book had not been written by the author's daughter, it would have been obvious to the discerning reader that Dr. Bauer is a father. Only a sympathetic and understanding parent could have learned as much about child psychology as he evidently knows. The whole period of childhood, from infancy to adolescence, is covered in this little book, and virtually every problem that modern parents encounter is discussed in a clear, sensible manner. While Dr. Bauer's sympathy is with the child, he also has a kindly feeling for the parent.

Perhaps the motif of the book is expressed in this sentence: "The great difficulty which children face in making their decisions is lack of experience." Over and over Dr. Bauer makes the point that children must learn by the trial and error method and that parents make a mistake when they interfere too much with this method. The adult should not often attempt to force his opinions on the child, even though they are based on his own experience, but should rather present all sides of a question, then let the child decide for himself, or herself. "Nine chances out of ten," Dr. Bauer says, "she will make the correct decision."

Dr. Bauer's book will not flatter the ego of many—indeed, of most—parents, but it should make every parent who reads it without prejudice understand his children better. The author's smooth style and the delicious flavoring of humor in every chapter make the dose palatable, even though it is strong medicine. Furthermore, those conscientious parents who have been led to believe that a child's entire life can be ruined by a few mistakes made in the early years of inexperience will obtain

comfort from the chapter, "Turning Over a New Leaf." One sentence is especially comforting: "In spite of parental fears and in spite of parental blunders, most children do turn out all right."

Another comforting thought is to be found in the chapter, "Parents Can Be Wrong," in which the author says: "The capacity of our children for loyalty and forgiveness is almost unlimited. . . . It is a marvel that children have such a terrific loyalty to their parents."

Dr. Bauer's book can be commended unreservedly to young and even not-so-young parents who want to do right by their children. Its author might well have paraphrased Ambrose Paré's famous sentence: "See how I learned to treat gunshot wounds; not out of books." Dr. Bauer, although he gives a list of books on child psychology for reference, might well say of his own book: "See how I learned to deal with children; not out of books."

Atlas of Cardiovascular Diseases: Correlation of Clinical Electrocardiography and Cardiac Roentgenology with Clinical History and Autopsy Findings. By Irving J. Trelger, M.D., Assistant Professor of Medicine, University of Illinois, Chicago. Cloth. Price, \$10. Pp. 180, with 69 plates. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1947.

The title page of this volume states that it is a "correlation of clinical electrocardiography and cardiac roentgenology with clinical history and autopsy findings." However, a careful study of the volume reveals many gaps in effective correlation. In the author's apparent endeavor to secure brevity he seems in a number of instances to have sacrificed clarity and effective discussion of the correlation of the observations. There are also several instances in which it is difficult to agree with his conclusions. One of the most striking examples is his statement that "correlation of history, physical findings, roentgenogram, and electrocardiogram leads to a correct understanding of the degree of anatomical and physiological changes in the heart and to a proper dose of various medications for their correction." One might agree, had the author said of a proper "selection" rather than "dose." Although in itself this is perhaps a minor misstatement, it could certainly prove highly misleading to the student or physician who was not too well acquainted with the subjects of pharmacology and therapeutics. This statement appears in the preface, but it is difficult, if not impossible, to find any elaboration of it in the context.

The illustrations are for the most part well executed, but unfortunately it is sometimes difficult to see in them the condition under discussion. For example, in plate 61 the legend mentions erosion of the thoracic vertebrae, but this condition is not revealed in the illustration.

Despite these shortcomings and others not specifically mentioned, the volume should prove useful to many as a source of graphic illustration chiefly of roentgenologic and anatomic observations in a fairly large range of cardiovascular diseases. In the hands of a competent teacher it might prove helpful as a basis for discussion of the various topics, the elaboration to be provided by the teacher.

However, when it is compared with some of the similar works on roentgenology of the heart and electrocardiography and their relation, it adds little of value to the existing literary armamentarium.

Dermatologic Clues to Internal Disease. By Howard T. Behrman, M.D., Assistant Clinical Professor of Dermatology, New York University College of Medicine, New York. Cloth. Price, \$5. Pp. 165, with 118 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1947.

Those who favor small books with brief discussions in outline form will find this book to their liking. The material is arranged alphabetically. The descriptions of various symptoms and syndromes, intended to serve only as clues, are concise but adequate, and the illustrations in general are well selected. Many eponymic syndromes are described. The common skin diseases and the exanthems are omitted, and there is no bibliography. By the use of cross references and the avoidance of repetition, the author has successfully restricted the size of the book and fulfilled his objective to furnish a book of clues for the correlation of certain cutaneous symptoms and systemic diseases. Also, he has managed to include his own opinion on certain problems; it is not just a cold compilation of material.

Molding and Casting for Moulage Workers, Sculptors, Artists, Physicists, Dentists, Criminologists, Craftsmen, Pattern Makers and Architectural Modelers. By Carl Dame Clarke, Ph.D., Associate Professor of Art as Applied to Medicine, School of Medicine, University of Maryland, Baltimore. Second edition. Cloth. Price, \$6.50. Pp. 300, with 99 illustrations. Standard Arts Press, 2635 N. Calvert St., Baltimore 18, 1946.

This is the second edition of "Molding and Casting." The present volume is larger than the first edition and its content of descriptive and illustrative matter has been considerably amplified.

The author explains the principles of technic in taking impressions and making casts. He describes fully the nature, behavior and method of manipulation of various types of materials used in these procedures. The use of plaster of paris molds, agar (hydrocolloid), gelatin, rubber and other substances is described, as are the various casting materials such as plaster of paris, wax and rubber.

While the book is of primary interest to medical artists specializing in plastic reproduction of anatomic and pathologic conditions, as well as in surgical procedures for making authentic records and for teaching purposes, it should find useful application in many other fields. Pathologists or anatomists who want to make their own preparations for use in classroom demonstration or lectures, preparators of museums of science and natural history and artists and craftsmen can all learn much from it.

This book should be useful to those interested in visual methods of instruction, particularly of a medical nature, as it explains the technic of preparing three-dimensional teaching aids, one of the most effective mediums of instruction. It gives numerous formulas for compounding material for taking impressions and making positive casts, which should mean considerable saving, provided that one has experience with such formulas.

One cannot help feeling that most of the chapter on "balsams, gums, resins, hydrocolloids and waxes" could have been left out, as a listing of such a large group of waxes, together with their physical and chemical properties, appears out of place in a book of this nature.

Since realistic appearance in most plastic reproductions of biologic specimens depends on fidelity of reproduction of color, in addition to reproduction of form, a more complete treatment of this all-important phase of the work would have improved the practical value of the book.

To the specialist the value of the book is naturally limited, but to the amateur it should prove a valuable guide.

Counseling in Schools of Nursing: A Study of the Principles and Techniques of Personnel Services for Students. By H. Phoebe Gordon, Assistant Professor of Nursing and Student Counselor, School of Nursing, University of Minnesota, Minneapolis; Katharine J. Densford, R.N., Professor of Nursing and Director, School of Nursing, University of Minnesota, and E. G. Williamson, Professor of Psychology and Dean of Students, University of Minnesota. Cloth. Price, \$3. Pp. 279. McGraw-Hill Book Co., Inc., 330 W. 42d St., New York 18, 1947.

This book provides excellent orientation for administrators, counselors, instructors, supervisors, head nurses and general staff nurses in the problems of student nurses and the guidance which should be available to them. It should prove valuable in the preparation of the personnel specialist or counselor. The authors are particularly well qualified by training and experience to present the subject of counseling in an authoritative and comprehensive manner. Part 1 provides the historical background of nursing and personnel work, while 2 and 3 deal with the understanding of the student, her problems in nursing and types of counseling which are necessary. Part 4 offers a practical approach to organization and development of a personnel program.

The importance of good counseling to the student, who is enabled to make the most of her opportunities, is stressed throughout. The hospital and patient benefit by improved morale and better adjustment of the student. The hospital administrator or director of the school of nursing who questions the necessity of instituting a counseling program will find convincing evidence in this little volume of its economy in the functioning of the hospital nursing service and the nursing school.

This book received the First Award of the McGraw-Hill Book Awards in Nursing Education.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

VENTILATION AND AIR BORNE INFECTIONS

To the Editor:—Will good ventilation without drafts in a nursery in southern California decrease the transference of air borne infections? Please cite references on the effect of improved ventilation on the infection rate. I find no articles on the use of ventilation for the control of air pollution.

Irving J. King, M.D., Los Angeles.

ANSWER.—In moderate amounts, ventilation is efficient in reducing the number of micro-organisms in the air and perhaps the infant mortality also. Too much ventilation, such as is used where the air pollution is heavy, may do more harm than good by stirring up infected dust particles off the floor. Blackfan and his associates have shown that other physical factors, such as temperature, humidity and "housecleaning," are more important than ventilation in the incidence of infection in premature infants.

TWIN PREGNANCY AND PERIOD OF INSEMINATION AFTER OVULATION

the Editor:—I am interested in the possibility of the relationship of the occurrence of twin pregnancy and the period of insemination of the ovum after ovulation. I know of 1 case of twins in which coitus occurred on the nineteenth day of the menstrual cycle in a woman whose cycle averages twenty-eight days. Data from readers would be appreciated.

Hugh Macdonald, M.D., Peoria, Ill.

ANSWER.—There is suggestive evidence from comparative embryology that deleterious influences exerted on the fertilized egg may increase the incidence of twinning. However, in man there is no apparent relationship between the occurrence of multiple pregnancy and the period of insemination of the ovum after ovulation. There are considerable data which would indicate that ovulation usually occurs about fourteen days preceding the onset of the next menstrual period. This interval is rather constant regardless of the length of the menstrual cycles. The ovum is capable of being fertilized for a short period following ovulation, probably less than twenty-four hours.

Monozygotic twins represent early segmentation of the fertilized ovum. Dizygotic twins result from two separate ovulations and the fertilization of both ova. Two egg twinning is definitely influenced by heredity, parity and age.

EFFECT OF SPLENECTOMY ON THE BLOOD

To the Editor:—A man sustained a fall in August 1946, rupturing the spleen and necessitating a splenectomy. He developed obstruction of the bowel twice following splenectomy, a pelvic abscess, collapse of the right lung and blood in the urine. He finally recovered. Blood examination after splenectomy revealed a leukocytosis of 46,000 gradually lowering to 13,000 at the present time with 59 per cent lymphocytes. There is 3 to 4 ounces retention of urine. Please give me the latest opinion on the effect of splenectomy on the blood. Does a high lymphocyte count cause extreme lassitude?

M.D., New York.

ANSWER.—Removal of the spleen is followed early by a mild anemia with the appearance of nucleated red cells, reticulocytes, polychromatophilia and Howell-Jolly bodies in the red cells and by leukocytosis and thrombocytosis. Some of these changes are thought to be evidence of an inhibitory effect of the spleen on bone marrow function. The anemia and thrombocytosis are bone marrow function. The anemia and thrombocytosis are transient, while in many cases there is a persistence of moderate leukocytosis with an increase in the lymphocytes and monocytes. Most patients have no symptoms following splenectomy, but some have been reported to have easy exhaustion and vague gastrointestinal complaints. There is no evidence of a relationship between mild lymphocytosis and lassitude.

PRESERVATION OF SKIN GRAFTS

To the Editor:—I have in mind the possibility of preserving the life of a piece of skin accidentally cut off until granulation tissue has formed on the denuded area, at which time the skin would be grafted onto the area from which it came. I would appreciate information on this or related subjects or the name of some other source of rather complete information on this subject.

M.D., Minnesota.

ANSWER.—Skin grafts may be refrigerated under sterile conditions and successfully transplanted after a number of days. They should not be frozen. Usually there is no reason for doing this. About the only reason, during an elective operation, for doing a delayed graft would be if the patient's condition became such, after the grafts had been cut but before they were applied, to justify stopping the operation without application of the grafts; the grafts could then be refrigerated and applied later.

In the event of avulsed tissue, one would be much more sure of a take by applying the avulsed skin to the raw surface in the shortest period of time possible after the accident. Of necessity one frequently applies skin grafts to a granulating wound, but it is much to be preferred to apply grafts to a newly created wound rather than await granulations.

About the only preserved tissue commonly used with success for subcutaneous grafting is preserved cartilage.

HOME WATER SOFTENERS

To the Editor:—In the July 1947 issue of *Consumers Research* an article by C. A. Tyler, Ph.D., on "Soft Water for the Home" says "If a softening system is installed, at least one tap (a cold water tap) should deliver water which has not been treated; water which has been softened should not be used for cooking or drinking." There is no further explanation. In your opinion, should softened water not be used for cooking or drinking?

A. J. Price, M.D., Canandaigua, N. Y.

ANSWER.—Home water softeners in their exchange of sodium for calcium in the dissolved salts in natural water may render the water less palatable, particularly if the "hardness" of the water is reduced to zero. A sudden change in the chemical characteristics of one's drinking water may cause some physiologic reaction.

The condition under which home water softeners are maintained and operated by persons inexperienced in water treatment may result in some contamination of the water.

For these reasons it may be desirable to install an additional cold water tap in the home. This does not mean however that in all cases softened water should not be used for drinking or cooking purposes. Public water supplies which are softened under technical supervision are usually so treated that both safety and palatability are assured and the supply is entirely potable.

PHLEBITIS

To the Editor:—Please let me know the accepted treatment for edema of the lower extremity in these two cases: 1. A man with no history of phlebitis or clinical evidence of phlebitis has a few superficial varicosities and a dilated saphena magna. Is ligation of the saphena magna indicated? If so, what is the rationale for ligation? 2. A woman has had a ligation of the saphena magna, as evidenced by a scar in the groin; there is still evidence of a dilated saphena magna extending three fourths of the way up the thigh and also some superficial varicosities. What means, medical or surgical, would improve or cure edema of the extremity in this case? Pelvic examination is negative in both cases.

Alexander Zabin, M.D., Malverne, L. I., N. Y.

ANSWER.—1. Lack of history of phlebitis does not rule out deep venous obstruction or deep valvular insufficiency, since many patients develop segmental venous obstructions in the deep veins without obvious clinical symptoms. More important is the presence of deep venous obstruction or deep venous reflux. If the saphenous valve is demonstrably incompetent in the standing position, the ligation of the long saphenous vein at its junction with the femoral vein is reasonable, since it removes the back-pressure from above; however, if the saphenous dilatation is caused in addition by incompetent perforators, they may have to be interrupted either by multiple ligations or by stripping out the entire long saphenous vein. If the valvular incompetence is in the deep veins, operations or injections on the superficial venous system will never be of lasting benefit, since the increased deep venous pressure will produce additional varicosities through perforator channels. In such cases well fitting elastic hose may be prescribed; more recently some authors have advocated the division of the superficial femoral vein below the profunda with the idea of decreasing the deep venous pressure in the leg. Such operations can be done only by men specially interested in this field and only in cases in which the disadvantages of the deep venous reflux outweigh the disadvantages of deep venous obstruction. Generally speaking, serious ankle edema with dilatation

of the saphenous system is more apt to be due to deep venous insufficiency, since uncomplicated saphenous varicosities seldom if ever produce ankle edema.

2. The presence of a dilated saphenous vein, in spite of a previous ligation, often means that the vein was insufficiently ligated and that the saphenous bulb is still patent with a number of tributaries. It is inadvisable for any one to ligate or inject such varicosities until he has satisfied himself as to the state of the superficial, communicating and deep valves. A pamphlet on varicose veins issued by the American Medical Association summarizes the necessary tests and the principles of treatment.

PROPHYLACTIC THERAPY IN PROLONGED LABOR

To the Editor:—It is my impression that prophylactic therapy with penicillin and one of the sulfonamides is used as a routine procedure at the New York Lying-In Hospital in cases of ruptured membranes after twelve hours. This is based on extensive research by Dr. Douglas at that institution. Have you any information concerning this or any like procedure in any other leading clinic? Martin E. Tyrrell, M.D., Depew, N. Y.

ANSWER.—In cases of premature rupture of the membranes without labor it is usually not necessary to prescribe prophylactic penicillin and sulfadiazine therapy. Experience has indicated, however, that when the membranes rupture prematurely and a desultory labor ensues such treatment is of great value. It may at times be instituted early in labor, but it should always be started, if possible, before twenty-four hours of labor. Experience has indicated that, if we wait until intrapartum infection has actually developed, the employment of the drugs is not nearly so effective as when they are employed prophylactically. Accordingly, it is necessary to predict complications such as prolonged labor, difficult delivery and trial of labor. The incidence of both intrapartum infection and subsequent puerperal infection can be greatly reduced by such treatment. It has also been shown that if a cesarean section becomes necessary after a trial of labor it can be done with a great deal more safety if the prophylactic therapy has been given.

The usual dose of penicillin recommended is 20,000 units given intramuscularly at intervals of three hours. Under certain conditions this dosage may be increased for a short period to 50,000 units every two hours. The sulfonamide of choice is sulfadiazine, and an adequate dose usually consists of 1 Gm. every four hours with about four times that amount of sodium bicarbonate. Occasionally it is necessary to give the sulfadiazine intravenously, and under such circumstances it is best to administer it with, or following, 500 cc. sixth-molar lactate solution. Experience suggests that the indications for prophylactic therapy arise in about 10 per cent of patients.

RELIEF OF PAIN OF INOPERABLE CANCER

To the Editor:—Please let me know the various accepted methods of relieving pain in inoperable cancer, especially carcinoma of the cervix, other than the use of narcotics.

Alexander Zabin, M.D., Malverne, L. I., N. Y.

ANSWER.—Three surgical procedures are generally used to relieve intractable pain associated with inoperable carcinoma of the cervix: chordotomy, pelvic sympathectomy and intraspinal injection of alcohol. Chordotomy, which consists of section of the anterolateral spinal tracts, will relieve pain, but it is an operation which usually requires the skill of a neurosurgeon. Unless the incision in the cord is accurately placed, the pain may not be completely relieved or the motor pathway may be damaged, resulting in paralysis of the legs and interference with control of the sphincters. The technic of chordotomy is described by F. C. Grant (*Am. J. Obst. & Gynec.* 24:620 [Oct.] 1932).

In pelvic sympathectomy the risk involved is slight, the technic is not complicated, and local infiltration anesthesia may be used for a large part of the operation. The type of operation usually performed is the one recommended by Cotté and consists in resection of the postganglionic fibers of the sympathetic nervous system which innervate the pelvic organs. The technic of pelvic sympathectomy is given by J. P. Greenhill and H. E. Schmitz (*THE JOURNAL*, July 1, 1933, p. 26).

Intraspinal injection of alcohol, which relieves pain by blocking the nerves that conduct pain sensation, is simple to carry out, entails very few risks and is highly effective in entirely or partially relieving pain associated with inoperable cancer of the cervix. The technic of intraspinal alcohol injection is given by E. L. Stern (*Am. J. Surg.* 25:217 [Aug.] 1934) and by J. P. Greenhill, and H. E. Schmitz (*THE JOURNAL*, Aug. 10, 1935, p. 406).

SEQUELAE OF CONJUNCTIVITIS

To the Editor:—A woman, a very intelligent nurse, aged 46, states that lid of her left eye is stuck to the cornea when she awakens. This has occurred fifty or sixty times in the last one and one-half years following a very bothersome conjunctivitis in both eyes. She keeps the membranes from sticking by the instillation of castor oil at night, the lids sticking in spite of this at times. When the lid and cornea are separated, there is discomfort, which disappears in about an hour. Examination is negative except for some superficial oval epithelium punctate markings at the lower margin of the left pupillary area. There seem to be a few of these in the right eye also. Her general health seems satisfactory. Her eyes are not subjectively dry, and a Schirmer test was normal.

M.D., California.

[This inquiry was referred to two authorities, whose respective replies follow.—Editor.]

ANSWER.—Occasionally after an attack of keratoconjunctivitis the cornea may remain more or less insensitive for a long time. There is also in these cases a reduced lacrimal secretion, although the Schirmer test may not reveal this. If one adds to these conditions some faulty closure of the eyelids during sleep, the corneal epithelium becomes dry and sticks to the tarsal conjunctiva, producing the symptoms mentioned. Treatment consists in use of a cod liver oil ointment, with 5 per cent glucose mixed in, applied in the conjunctival sac before retiring, and the use of a "moist chamber" covering during sleep.

ANSWER.—This patient may have had an allergic conjunctivitis with a superficial punctate keratitis. Epithelial infiltrates are common findings in long standing conjunctival allergies. In such cases one drop of Lugol's solution in ½ ounce of 1 per cent potassium iodide, used three times a day, allows clearing in a few weeks. A boric acid ointment at night prevents discomfort on awakening in the morning.

PITYRIASIS OR TINEA VERSICOLOR

To the Editor:—A woman aged about 30 consulted me three years ago with regard to a discoloration or pigmentation on the breasts about the size of a silver dollar which in a few weeks spread slowly to her shoulders. It is now down as far as the navel in front but only on the shoulders on the back and up the neck on the sides. It spreads slowly and in patches, some as large as my double hands and solid, and good skin is mingled with the pigmentation. The skin isn't raised and is smoother than normal skin but rather brown, and on some days red. It itches somewhat when she gets hot. It seems to scale off slightly and these particular spots feel dry. There is no pain. I first gave her Coffron Capsules, which didn't seem to help; then I gave her Thio-Bismol shots every other day for some time, then two each week. This was about two and a half years ago and it seemed to help some. During this time the discoloration was only on her shoulders. I thought she was getting along well and so stopped the shots. As time went on it got worse, so I gave more Thio-Bismol shots but didn't get as good results as at first. I took a blood test in 1942 and another in 1945 and both were negative. The temperature is 98.2 F., the blood pressure 112/60, the pulse rate 72. Specific gravity of the urine 1.027, slightly acid, no sugar, and slight albuminuria. The teeth are in fair condition.

M.D., Missouri.

ANSWER.—These pigmented spots, of various sizes and designs, with mild scaling probably are those of pityriasis or tinea versicolor. In this disorder there are slightly raised patches and sheets appearing on the flanks, usually not spreading through the midlines, and in extreme cases they may cover the entire torso. The patient develops a slight furfurescence or powdery scale which can be best appreciated by scraping the affected parts. At times the lesions are reddish, especially when they are irritated or after friction and sweating. There may be some itching. The lesions commence at the site of the follicles and then spread and coalesce with neighboring ones to form patches. This infection is said to occur in those who are given to much sweating and is commonly believed to occur more frequently for that reason perhaps in tuberculous subjects. This impression has not been verified by some observers. It is true, however, that some persons are subject to this disorder, and even though the apparent trouble is cleared, it tends to recur in them. The infection is due to a fungus called *Microsporon furfur*, which lives on the surface of the skin and produces changes in the very superficial parts. The organism really should be classified as a saprophyte rather than one which produces any real pathologic condition. Treatment can be carried out simply with about 12 per cent sodium thiosulfate solution in water, sponged on the parts twice a day until they are cleared. Whatever the topical method used, it should be continued for an appreciable period after the lesions disappear. Other methods which have been employed with success are mercury bichloride water solution 1:5,000, a 3 to 5 per cent sulfur treatment and Whitfield's ointment (best carried out in ¼ to ½ strength).

This fungous infection has no effect on the general health and does not require any radical treatment. It tends to relapse. In those who are subject to it, simple treatment such as with the sodium thiosulfate solution may be continued twice a week after the lesions have cleared.

EXFOLIATIVE DERMATITIS

To the Editor:—A woman aged 20, with a history of rheumatic heart disease from childhood, developed symptoms of arthritis in March 1947. She was given a course of penicillin therapy amounting to about 1,500,000 units. In April several areas of redness and scaling on her body and seborrheic eczema of the scalp and ears developed. Subsequently exfoliative dermatitis involved the entire body. When first seen by me on June 19 the patient appeared extremely ill, with rapid pulse, temperature 102.6 F. and oozing from fissured areas in the folds of the body, with a profuse purulent discharge from both ears, swelling of the hands and feet and fissuring on the dorsal surface of the toes. After admission to the hospital her temperature dropped to normal within forty-eight hours. Culture of the ear discharge showed a pure growth of *Proteus vulgaris*. Urinalysis was negative. The blood counts ranged from 10,500 to 21,000 white blood corpuscles. The erythrocytes dropped from 3,750,000 to 2,750,000, and the hemoglobin from 68 per cent to 59 per cent. The differential count varied from 35 per cent to 58 per cent of polymorphonuclears. The lymphocytes ranged from 92 to 5 per cent. There was a slight shift to the left. Blood culture was negative. During the hospital stay all the fissures except those in the toe region were healed, but the exfoliation and the ear drainage continued. There is a considerable loss of hair. The lymph glands, liver and spleen were not enlarged. Is it possible that this condition could be a penicillin reaction or a preleukemic condition? I would appreciate any suggestion.

M.D., Florida.

ANSWER:—Skin eruptions following the use of penicillin are extremely variable. The commonest type of eruption following its use is urticaria, but maculopapular and erythematous lesions are not infrequent. Bullous lesions and exfoliative dermatitis have likewise been observed. The severe cases of exfoliative dermatitis that have been described rarely last more than three weeks. In the case under discussion, the nature of the onset of the eruption and its long duration, together with the profound changes in the blood, would make one question the diagnosis of penicillin sensitivity. The vast majority of eruptions appear within five to twenty-one days after penicillin is started and rarely persist more than twenty-one days after their appearance. Careful patch testing with penicillin might provide information concerning penicillin sensitivity.

APPLICATION OF SILVER NITRATE TO THE EYE

To the Editor:—My wife has been advised by an eye doctor to use silver nitrate. He himself applies it. It makes her quite uncomfortable. A member of the board of ophthalmology states that he has not used this in years. Please advise.

M.D., Alabama.

ANSWER:—Silver nitrate is extensively used for the prevention of ophthalmia neonatorum and in the treatment of mucopurulent conjunctivitis, trachoma, blepharitis and many other conjunctival inflammations. Its effect is due largely to a caustic action which coagulates superficial layers of the conjunctival epithelium, forming a bluish white eschar which is washed, wiped or cast off in flakes. Silver nitrate is not strongly antiseptic, but organisms are entangled in the coagulum and removed with it. A secondary effect arises from the irritation, which causes a hyperemia and flooding of the part with serum. The pain caused by application of the drug may be relieved by cocaine.

All silver salts are irritating to the eye, the degree of irritation paralleling the concentration of the drug used and to a great extent dependent on the nature of the salt used. Long continued use may result in the deposit of silver in the tissues (argyrosis), a condition which may rarely follow relatively few applications. Local application delays epithelization of the abraded cornea, and blindness has been known to follow the use of too strong a solution. Thus extreme care must be exercised whenever silver salts are used.

MONGOLIAN IDIOCY AND CRETINISM

To the Editor:—Are there any tests other than clinical examination to differentiate between mongolian idiocy and cretinism? How can one determine the basal metabolism of an 8 month old baby other than by direct calorimetry?

L. A. Crowell Jr., M.D., Lincoln, N. C.

ANSWER:—It is usually possible to differentiate between mongolian idiocy and cretinism by the appearance of the patient. In occasional instances there may be some doubt as to the exact diagnosis and under these circumstances the two conditions can usually be differentiated by a therapeutic trial of desiccated thyroid. The initial dose for an 8 month old baby should be $\frac{1}{4}$ grain (15 mg.) of U. S. P. thyroid daily.

Direct calorimetry is carried out in only a few clinics in the country, and the results of basal metabolism determination in babies and very young children are open to question. In most instances in which the diagnosis is in doubt it is preferable to make a therapeutic test with desiccated thyroid rather than rely too much on basal metabolism determinations.

SEVERE BACK PAIN

To the Editor:—A veteran, 35, had his first severe episode of back pain while in Hollandia, New Guinea, and since then has had three recurrences of severe pain twice on the left side and once on the right side, typical of renal colic. Opiates relieved the pain. Red blood cells have appeared intermittently in the urine during and between the attacks. Two competent genitourinary surgeons have made thorough studies by cystoscopy, retrograde and intravenous pyelogram. No cause for the condition has been determined. Gallbladder, gastrointestinal x-rays and barium enema are negative. The blood count is normal. Stool examinations have been repeatedly negative. A centrifuge specimen of the urine on two occasions contained a small shiny red round object which we have been unable to identify. Is there a tropical disease endemic to New Guinea which could in some way be responsible for the occasional recurrences simulating renal colic?

M.D., New Jersey.

ANSWER:—Schistosomiasis is a tropical disease which could cause symptoms as outlined. Cystoscopically, schistosomiasis is characterized by small papillomatous and granulomatous lesions about the ureteral orifices. However, adnexal disease could also cause these symptoms. Vesiculitis in particular can cause hematuria and ureteral colic because of the proximity of the vesicle and ureter.

RETREATMENT OF SYPHILIS DURING PREGNANCY

To the Editor:—What is the best month for retreatment of syphilis during pregnancy? I have a patient who was treated for secondary syphilis in September 1946. She received 4,500,000 units of penicillin (50,000 units every three hours) as well as ten injections of oxophenarsine hydrochloride and four injections of bismuth subsalicylate in oil (1 cc. each). Her serum reaction, which was strongly positive at first, became negative in about six months and has continued so. At present she is going into her fourth month of pregnancy. I would appreciate knowing when retreatment should be started with penicillin and with what dosages; whether oxophenarsine hydrochloride and bismuth should also be given and whether a spinal tap should be taken and when. The husband has also been treated for the same condition and has likewise been negative since March.

M.D., Connecticut.

ANSWER:—It may be that the patient is cured and that there will be no danger of the fetus being infected. However, in view of the comparatively innocuous character of the remedy employed, we would recommend that in this particular situation the patient be given a daily intramuscular injection in alternating buttocks of penicillin calcium (peanut oil in beeswax) 300,000 units for a series of twelve injections. Moreover, the fourth month would be an ideal time to administer the treatment. In view of the almost specific effect of the drug in syphilis in pregnancy, no further treatment with heavy metal is necessary. A lumbar puncture is not recommended during pregnancy but should be done sometime after the birth of the baby. It would be well to continue the monthly titrated serologic test on both wife and husband until such a time as they have been completely negative for one year. Moreover, after delivery the child should likewise have a titrated serologic test beginning with the cord blood and at the second, fourth, sixth and twelfth month. It is only by the titrated test that the true situation can be properly followed. A rise in the curve that persists and continues to increase indicates syphilis and imminent relapse.

TUBERCULOSIS AND WIND INSTRUMENTS

To the Editor:—Kindly advise me whether it is harmful to allow an adult patient with a healed pulmonary tuberculosis lesion to play a wind instrument.

M.D., New York.

ANSWER:—If the tuberculous lesion is completely healed, the answer is easy: in early or moderately advanced disease no particular harm can arise from blowing a wind instrument; if the disease was far advanced and the lung parenchyma over half destroyed, there would be a risk of producing or aggravating an emphysema, which practically always accompanies a far advanced healed disease.

Since few patients or physicians can always know whether complete healing has taken place in any given case, it is difficult to say just when such strenuous exercises can be begun even in early cases. A safe rule would be to have a negative stomach lavage for tubercle bacilli for at least two to three years after the usual clinical arrest of the disease.

PREGNANCY AND HODGKIN'S DISEASE

To the Editor:—Referring to a Query and Minor Note, "Pregnancy and Hodgkin's Disease," *The Journal*, Oct. 4, 1947, page 318, I submit the following reference: Kushner, J. Irving: Pregnancy Complicating Hodgkin's Disease (Lymphogranuloma Malignum), *Am. J. Obst. & Gynec.* 42:536-538 (Sept.) 1941, in which the history of a patient with pregnancy complicated by Hodgkin's disease is reported. This patient received radiation therapy during the early months of her pregnancy. A healthy child was born, whose subsequent development was normal.

J. Irving Kushner, M.D., New York.

PSYCHOSOMATIC DIAGNOSIS

ANDREW D. HART, M.D.
Charlottesville, Va.

Psychosomatic medicine represents an orientation in medical philosophy and practice, a perspective that attempts to evaluate the relation of personality factors and life situations to disease. Psychosomatic diagnosis thus depends on a discipline that requires, in addition to a knowledge of the manifestations of disease, a further understanding of its nature and its significance to the patient in terms of personality security. It is in this specific significance, this utility to the patient, that psychosomatic illnesses primarily differ and in a broad classification may be distinguished from other diseases. Many chronic illnesses produce changes in life situations that require some measure of personality adjustment. In many other diseases personality factors operate to permit a utilization of the illness for secondary gain, with resultant protraction of symptoms and disability. Yet a still broader segment of disease may be considered as primarily psychosomatic in that the structural alterations of the body, and various psychologic manifestations as well, arise from specific patterns of reaction to personality conflict and insecurity.

Patients with psychosomatic disease may show little or no evidence of emotional instability. The outward tension phenomena commonly associated with a neurotic disposition and with the psychoneuroses are often absent; the energy related to anxiety is effectively channeled in physiologic expressions of symptom formation. Such patients may feel that they have "inward nervousness," and indeed their calm and sometimes phlegmatic temperament is often abruptly lost if insecurity becomes excessive or if the walls of resistance built up around their illnesses are jeopardized. In psychosomatic illness, insecurity conflicts have been persistently and deeply repressed, substitutive symptom formation thoroughly established, and the whole complex reactive pattern hedged and protected with resistances. It is in the study of these resistances, which are so clearly shown in the attitudes and behavior of many patients and defensively overelaborated to the point of discrepancy, that a positive and rapid diagnostic key to the nature of the disease may be found.

The psychologic expressions and physical symptoms of primary psychosomatic disease derive from and are part of a conditioned biologic response, a total body illness that is dynamically determined and basically purposeful to the life of the patient. Studies of the significance of this purposefulness of the illness indicate its relation to integration of personality—its

development as a total organism compromise in an interaction of unconscious dynamic forces that perhaps threaten more serious and costly alternatives in adjustment. Thus primary gain is inherent in the protection afforded to the personality integration and identity of the person. Likewise, factors of secondary gain commonly become operative. Viewed in the framework of these considerations, the value of the illness to the organism and the basic dilemma of the patient are apparent. Although an ill person must consciously and rationally attempt to seek relief for manifest symptoms and disability, there are unconsciously motivated resistances to such attempts that block their success. Indeed, it might be expected that every dynamic resource of the organism would be called into action to protect the illness and maintain its expressions until the greater threat to personality security had been lessened or resolved. That such is in fact the case is attested by observation of patients' resistances: in attitudes, in free association and in specific behavior. Some of these resistances, noted with brief comment and illustrative case material, will be reported herewith.

RESISTANCE SYMPTOMS

Procrastination in Seeking Medical Attention.—Patients with psychosomatic complaints are seldom seen early in the course of their illnesses. Medical care is sought with reluctance, often only at the repeated insistence of relatives or friends. Not uncommonly it is months before the patient "gives up" and submits to an examination. This willingness to temporize is usually inappropriate to the severity of complaints and to the extent of the disability. It constitutes a discrepancy in behavior that is rarely observed in patients whose diseases are primarily due to external agents or unaccompanied by significant personality disturbance.

A farmer, aged 40, was brought to the hospital by ambulance after a sudden massive intestinal hemorrhage. His wife stated that he had suffered from stomach pains and dyspepsia periodically for the past five years but had never had any treatment except sodium bicarbonate, self prescribed. In spite of urgent requests from his family he had consistently refused to consult a physician. The patient was found to have a large duodenal ulcer. When later questioned as to why he had put off medical attention so long, he replied vaguely that he had so much work to do that he couldn't "find the time." Actually his symptoms had frequently prevented him from working for days. When this discrepancy was pointed out to the patient he stated lamely that on such occasions he felt too bad to go through with a lot of examinations.

Self Treatment.—Many patients indulge in self diagnosis and protracted self treatment, despite the availability and rationale of adequate medical care. Although it is normally optimistic to hope that an acute or mild illness will be resolved with time and a few comforting household remedies, to maintain such expectations in

From the Department of Internal Medicine, University of Virginia School of Medicine, Charlottesville, Virginia.

the face of chronic discomfort and disability represents an illogical and discrepant attitude. It is perhaps the most reliable characteristic of patients with psychosomatic illness that in submitting to medical care they reserve for themselves a greater independence of action in decisions as to choice of procedure and detail of treatment. The attitude is "fussy," rigid in limitations and demands, and gives the unmistakable impression that they need to manage the case themselves. When such patients put themselves "entirely in your hands" either they are extremely ill or because of some motive that may be later revealed they are expressing a wish opposite to their unconscious intention and subsequent behavior.

A bookkeeper, aged 42, was brought to the clinic by his sister, who stated that he had complained of stomach symptoms intermittently for three years. At times his discomfort had been severe and disabling, with pain, nausea, vomiting and continual eructation of gas. The patient appeared to be convinced that his illness was caused by food idiosyncrasies and had eliminated one article after another from his meals. In addition, he experimented extensively with food fads and a variety of patent medicines. Early in his illness he had consulted a physician, once, and did not return because roentgenograms of the stomach which he thought "unnecessary" had been advised. On the present occasion the patient was found to have pyloric scarring from previous ulcer and a moderate degree of obstruction related to spasm. Arrangements made for treatment were not subsequently carried out by the patient.

Sabotage of Treatment.—In a competitive and energetic society a considerable amount of social pressure is exerted on persons that are chronically disabled and complaining to provoke them to seek orthodox medical care. The number of individuals with psychosomatic illness who pay lip service to treatment, who go through the motions of adhering to some plan of improvement, is certainly legion. A catalog of the specific devices by which treatment may be counteracted and nullified becomes a pageant of rationalizations—all the devious means that persons employ to avoid doing what they consciously should do but unconsciously feel that they cannot do now. Physicians are more familiar with the acts of omission—broken diets, renewed habits, unfilled and unopened prescriptions, forgotten medications, fractured routine and disregarded advice—than with the basic significance of such behavior as compulsive, positive neglect that is specifically and dynamically purposeful.

An active physician, aged 43, was referred for cardiovascular study on account of recurrent symptoms of angina pectoris, first noticed five years previously. At age 40, following a moderately severe attack of pain, electrocardiographic tracings showed bundle branch block of the S wave type; previous electrocardiograms had been normal. Present studies revealed no significant abnormalities except a slight elevation of blood pressure and the heart block previously noted. This patient repeatedly indicated a desire to follow a moderately restricted and healthful regimen as carefully outlined by his physician. Actually, there was no real reduction in his compulsive overactivity. Directions as to midday rest, avoidance of tobacco, reduction in weight and limitation of work were not seriously entertained. An effort to improve life situations productive of insecurity and directly related to the cardiac symptoms was initiated and maintained with tardiness and great difficulty.

Broken Appointments.—The basic dilemma regarding treatment is shown more strikingly in the psychoneuroses, particularly when clear outward evidence of structural disease is lacking. An alignment of the forces for and against treatment is less subtle, the resistances rather ill concealed. In many instances only an

initial appointment is kept and it is apparent that the person has acquiesced in consulting the physician as a gesture only and is not seriously entertaining plans for treatment. The rationalizations in support of this behavior are rather gross: the patient finds it impossible to meet the physician's hours, impossible to take time from his own work, impossible to spend relatively small sums for treatment even when disability is causing much greater loss. The impediments to adequate medical care become many and insurmountable. Enthusiasm for treatment in a patient with chronic psychoneurotic illness is itself a rationalization and usually indicates that the patient will break treatment at the first opportunity.

A railway employee, aged 45, gave a history of excellent health prior to the onset of his present illness two years before. Since that time he had suffered continually from gastrointestinal complaints and from depression over his "inability to perform any useful work." His illness had cost over \$10,000 in loss of income and expenses. After months of urging, this patient had been finally persuaded by his local physician to come to a large medical center for thorough examination and treatment. When first seen, he expressed much enthusiasm and gratitude for this opportunity at last to "get at the seat of my trouble." Before the laboratory and roentgen studies had been completed, this man abruptly stopped his clinic visits, writing later that the examinations had taken too long and that the expense was more than he could bear.

Medical Shopping.—The addition of many intelligent patients to medical "window shopping" requires explanation. Numerous physicians are consulted one after another without giving any of them a satisfactory opportunity for systematized investigation of the illness. The common refrain "doctors do not understand my case" is as frequently related to the obstructive attitude and behavior of such patients as to the unskilfulness or lack of interest of physicians who attempt to treat them. The motives behind medical shopping are usually associated with an unconscious need for retention of the illness.

A man 40 years of age, whose chronic symptoms referable to the upper part of the gastrointestinal tract represented an anorexia nervosa equivalent, admitted that he had consulted fifteen different physicians during his two year period of illness. In each instance he had changed physicians after a few preliminary visits. Ignoring the fact that only limited occasion had been provided for study of his illness, his attitude expressed a need to regard his condition as obscure and misunderstood. This patient's home medicine cabinet was stocked with many partially tested prescriptions.

Limitation of Treatment.—Behavior outwardly opposite to medical shopping but similarly motivated is expressed in adherence to limited specialistic forms of diagnosis and treatment. In spite of the presence and persistence of general symptoms, a single major complaint is assumed by the patient to be the only significant abnormality; particular treatment for it is undertaken year after year, to the vigorous exclusion of more complete investigations. A frequently reiterated statement familiar to physicians is: "There is only one thing wrong with me and if I can just get that cured I will be all right." Popular trends toward extensive specialization in medical practice encourage such circumscribed treatment, and in this setting the broader aspects of psychosomatic illness may be effectively neglected.

A woman, aged 45, gave a history of chronic nonseasonal nasal obstruction—"chronic sinus"—that had caused inconvenience and partial disability for twenty years. During this entire

period she had remained under treatment for the local complaint, alternating groups of visits between her rhinologist and allergist. Several operations on the nose and accessory nasal sinuses had been performed. Belated attempts to secure for this patient a general medical study that would include an evaluation of other important symptoms were met with persistent opposition.

Patronage of Cults.—Patients with psychosomatic illness have a strong leaning toward treatment by unorthodox practitioners and substandard methods. This trend may be seen in a willingness to accept lay advice, hopeful reliance on patent remedies, an enthusiasm for medical fads and support of the cults. There is an inappropriate bent and loyalty to methods and systems that temporize with illness through policies of suggestion, reassurance and palliation. Such patients plainly show a need for constant symptomatic treatment instead of a recourse to serious investigation of the nature and cause of the total problem of their illness.

An active successful business man of middle age was referred for diagnostic study on account of the recent development of precordial pain. Routine investigations disclosed moderate heart enlargement, rather severe hypertension (230 systolic and 130 diastolic), and minor electrocardiographic defect. Renal function was not measurably impaired, nor was prostatic obstruction demonstrable. The large peripheral arteries were not perceptibly sclerotic; however, there were distinct changes visible in the vessels of the retina. This patient, on his third visit, "recalled" that high blood pressure had been noted four years previously during an insurance examination and that insurance had been denied. At the time, he had been actively involved in business matters and was suffering from fatigue and "nervous headaches." Although he had been advised to obtain a careful medical examination, the patient decided instead to try chiropractic treatment, which had been continued regularly since. In spite of the admitted fact that the relief from manipulative treatment had been transient and minimal, the patient expressed great satisfaction with his "adjustments" and some concern lest he be requested to discontinue them.

Vagueness and Evasiveness.—Practitioners are familiar with the tendency of many patients to confuse and obstruct medical study by a vague and incoherent recital of complaints. The actual facts of the history such as the date of onset, the exact nature of symptoms and the time of appearance of additional factors in the illness may be forgotten, or recalled with uncertainty and seeming indifference. To wrest an accurate and sequential history from such a patient may require more labor and patience than the physician is willing or able to expend. When purposefully led into a digression—some subject unrelated to the illness—the patient may show an alertness, interest and mood quite at variance with previous diffidence. Exhibited in an intelligent person, vagueness represents an unconsciously motivated technic of resistance.

A salesman, aged 36, complaining of palpitation, shortness of breath on exertion, sharp transient pains over the precordium and inability to work, was referred from a cardiac clinic where a diagnosis of neurocirculatory asthenia had been made. Attempts to secure a consecutive history of the illness were at first unrewarding; the patient's entire attitude was one of vagueness and indifference, of allowing the examiner to probe for and approximate the salient facts. When asked the nature of his trouble the patient countered, with some satisfaction: "That's what I came here to find out." Several interviews were required to overcome a tedious and frustrating game of hide and seek for the pertinent details of the history. Led into topics unrelated to the illness and the insecurity conflicts involved, this man talked with clarity and responsiveness.

Circumstantiality.—Akin in motive to vagueness, excessive preoccupation with irrelevant detail is a common symptom in psychosomatic illness. In an endless and seemingly trivial and digressive recitation, the core of any important question may be avoided and go unanswered. The digressive material is too foreign, too remotely connected with insecurity conflicts to serve a specific ventilative function. Circumstantiality is certainly a pressure of speech, as any physician will testify, but it is more related to a habit of garrulousness than to the cathartic speech pressure encountered in initial interviews of patients with tension and anxiety, and its value from the standpoint of free-associative information is almost nil. Circumstantiality may be regarded practically as a resistance symptom that permits the patient to filibuster, to keep the floor and avoid a direct and pertinent approach to the basic problems of the illness.

A chair-ridden woman, aged 50, was observed frequently during a period of six weeks in an attempt to initiate beneficial treatment of moderately advanced deforming arthritis and accompanying symptoms of tension, fatigue and debility. Since the beginning of her arthritic symptoms, five years previously, this patient had successfully resisted efforts to institute their appropriate treatment. On the present occasion, attempts to obtain information relative to the total illness and to the personality factors involved were constantly obstructed by the patient's ready circumstantiality and distractibility. Each consultation period was flooded with exhaustive details of her numerous symptoms, feelings and political reflections and the remarks and characteristics of her family and friends. Efforts to steer the sense of the interviews into a connected framework were repeatedly blocked by digression. Reliable reports of the external contributory factors in this patient's illness had to be obtained from members of her family.

Complacency.—The classical attitude, "la belle indifférence," so commonly observed in hysterical conversion, has a counterpart in the masked diffidence that usually accompanies psychosomatic illness, particularly if the disease has progressed to some tangible and socially recognized pattern of structural defect. In addition to the primary utility of the illness, factors of secondary gain are often in operation; the patient's unconscious and sometimes conscious needs to retain the symptoms are reflected in resistances to their significant relief. Thus in psychosomatic illness the patient is confronted with a basic behavior dilemma: a rational need and external social pressure to find relief for illness and disability; an opposing internal, compulsive, dynamic and unconscious need to perpetuate the conditioned biologic response to threats or assaults or situations that engender insecurity. A clear and familiar illustration of the result of this fundamental opposition of forces may be recognized in "simple" obesity, a psychosomatic condition in which resistances to treatment are obvious and later admitted—despite their versatile disguises.

A housewife, now aged 40, stated that her average weight had been 115 pounds (52.1 Kg.) until ten years before. At that time, after a period of tension, weakness, fatigue and restlessness related specifically to change and insecurity in her life situation, she began to gain weight rapidly. With the exception of minor remissions (30 pounds [13.6 Kg.]) due to painfully forced dieting, her average weight for the past nine years had approximated 200 pounds (90.7 Kg.). During this period the patient had submitted to many examinations, had experimented irresolutely with special diets, exercises, massage, gland extracts and similarly accredited but really inappropriate measures. No plan of treatment had been loyally maintained beyond a few months. Prior to her illness this patient had

worked as a model, was rather noted for her attractive appearance. An intelligent person, she was aware of the longevity statistics relating to overweight and not insensitive to the esthetic implications and physical discomfort inherent in her obesity.

Relief Afforded by Physical Defect.—The significance and role of resistance phenomena in psychosomatic disease are adequately confirmed by observation of accompanying attitude and behavior symptoms that clearly indicate a need for the development of physical manifestations. The utility of demonstrable structural abnormality is shown indirectly in the zeal with which patients often search for tangible defect, their almost obsessive conviction of its presence and the obvious relief that follows the detection of a minor alteration of the body even if patently unrelated to the prominent symptoms. Many patients are frankly conscious and expressive of this need: "Doctor, if you can just find *something* the matter, I will be all right; I have been to so many doctors and they cannot seem to discover the trouble or understand my case." Inconsequential and borderline deviations from the normal, discovered years before, may be recalled and hopefully accorded an emphasis that could not be logically warranted.

An infantry soldier, aged 36, complained of severe headache of the muscle tension type which had developed three weeks previously after an exhaustive combat experience. No recent injury had been sustained; the patient had not been exposed to blast effects. Physical and neurologic examinations were normal. Evidences of tension and fatigue were pronounced. This man was convinced that his headache was due to unresolved results of a cerebral concussion experienced nine years before, although recovery from that injury had been uneventful and there had been no interim symptoms or disability. The occipital protuberance, apparently just discovered by the patient, was hopefully indicated as a sign of recurrent trouble from the old accident.

When the need and quest for physical defect is strong, symptoms of hysterical type may be projected, involving topographically "weak" areas such as scars, symbolic locations, or as conversion overlay phenomena complicating the patterns of physiologic dysfunction and structural change in psychosomatic disease and, as well, in other forms of disease or injury.

A soldier with "combat fatigue" and progressive anxiety symptoms sustained a penetrating flesh wound of the thigh and was evacuated to a general hospital for treatment. Nerve injury was absent. Coincident with surgical healing, complete anesthesia developed with "paralysis" of the entire lower limb. When this complication was shown to be hysterical in nature and the function of the limb restored, severe anxiety symptoms reappeared and the patient complained of pain and weakness in the area of an old herniorrhaphy scar.

The dynamic forces underlying accident proneness are worthy of further study in relation to their similarity to the mechanisms under discussion. It is seldom that persons subject to repeated accident do not indicate in some indirect but significant manner the basically purposeful negligence associated with their injury. A recent patient, in recurrent depression and under particular circumstances requiring a cloak for manifest disability, stated after her third accident: "I wish I could have ended it all when I hurt my back." The beneficial effects of intercurrent illness on persons suffering from psychoneurotic disease have long been noted by practitioners and have been the subject of a recent report. Of searching interest and significance will remain the often prompt and satisfactory relief

of tension and anxiety that so commonly follows the development of physical symptoms and tangible structural defect.

A woman, aged 37, was observed over a period of two years for tension and fatigue symptoms related to domestic maladjustment and personality insecurity. During this time repeated examinations were requested and performed to exclude pulmonary tuberculosis, which the patient feared obsessively "on account of an early family contact." Abrupt cessation of anxiety and general complaints occurred when chronic non-seasonal bronchial asthma developed. The patient expressed great relief "since the first attack of wheezing," and insisted (perhaps with accuracy) that the asthma had been "under the surface all the time." Allergy studies could not be obtained due to inability of the patient to "feel a need or find the time for further medical work now."

Fear of Personality Study.—Along with a conviction of physical defect—a wishful self persuasion that the illness is "entirely physical" perhaps founded in the converse fear that it is possibly "mental"—many persons with psychosomatic illness exhibit hypersensitivity and intolerance to personality study. This resistance, often firm and aggressive, finds its greatest expression in the frank refusal of the majority of patients to undertake psychiatric interview even in a preliminary or tentative way, and constitutes an effective block to any formal psychiatric treatment of psychosomatic disease on a broad statistical scale. Even in routine medical study, tactless or hasty methods of approach to personality inventory may lead to open dissatisfaction, anger, letters of protest, refusal to follow ordinary clinical procedure, and not infrequently lead to the patient's quitting the hospital or the physician. Such behavior assumes particular significance at active medical centers, which may be considered "courts of last resort" for many sick persons. After long chronic illness and disability and expense, after repeated trials of new medicines and new physicians and after general failure to recover or improve, the patient has been persuaded to make the necessary arrangements, undergo a long trip and submit to hospitalization. All of this effort, clearly the last to secure what must be thought to be expert study and treatment of the illness, is often inconsiderately thrown away. So bright a discrepancy in behavior demands explanation. Although it is beyond the scope of this report to discuss in detail what is known of the dynamic forces operative in such behavior, one fact seems apparent, the patient's need for an approach to recovery by this particular medical plan is outweighed by other necessities of the illness.

After three years of partial invalidism and extensive medical treatment for chronic idiopathic ulcerative colitis, an attorney aged 38 was persuaded to repair to a nationally prominent medical center for thorough study and treatment. Examination showed an inwardly tense, undernourished and slightly anemic person whose numerous daily stools contained much blood. On the hospital ward it was observed that the patient was intensely occupied with the rituals of his toilet, with petty details of his diet, with a slight inconstant elevation in temperature and with the art of securing a variety of medicines to guarantee sleep. An accurate medical history was obtained with much difficulty, the patient appeared strangely disinterested and repeatedly interrupted the interview to reiterate: "I know my trouble is due to an infection of some sort," and "there isn't anything mental in my case." An attempt to discuss common personality characteristics, in the most gradual and oblique manner, could not be tolerated by the patient, whose protests continued to be excessive and rationalistic. He became increasingly obtuse, difficult and demanding and finally left the

hospital after a total stay of six days, stating that proper treatment had not been started and that he was "too ill to be away from home and his local doctor."

Denial of Conflict.—Patients with psychosomatic disease frequently resist pertinent study by an initial and often persistent denial of significant personality insecurity or conflict. The protective need to maintain that personality factors are not concerned in the illness leads to illogical and unwarranted optimism and to a further minimizing of serious insecurities, situations and performance deficits. Their lives could not possibly be as secure and free from stress and worry as some of these persons (unconvincingly) describe them. If the physician probes prematurely in a search for conflict or associated repressed material, these patients' attitudes will become noncommittal and evasive, leading to the unmistakable impression that more is known than can be told. It is significant that numerous voluntary denials may be offered and repeated, for example: "I can't imagine what is making me so ill"; "I've told you absolutely everything I know"; "I wish I knew more about myself to tell you." If these patients remain under treatment they will surely find out more about themselves and their illness to tell, including an admission that they did not feel able to talk freely at first. This behavior is so commonplace that an illustration appears almost superfluous.

A woman of middle age who complained of severe and frequent migraine attacks insisted that her home life was secure and happy and went voluntarily into considerable detail to emphasize the congenial relations that existed with her husband and within her family circle. During this description, however, she frequently and perhaps ostentatiously displayed her left hand, on which no wedding ring could be observed. After several consultations in which examinations and discussions were deliberately restricted by the physician to the details of the headache symptoms, this patient became more confiding and in a sudden flood of emotion revealed a distressing and seemingly hopeless domestic situation later shown to have been a precipitating factor in her present illness.

Misleading Explanations.—Many patients with severe and deeply repressed conflicts unconsciously resort to devious methods of preventing their disclosure. If interrogation becomes too pertinent, substitute anxiety situations may be offered as plausible causes for worry and distress. The physician must note the discrepancies in these misleading explanations, evaluate the deeper resistances that provoked them, and proceed more gradually and cautiously in treatment.

A patient who had persistently denied any known cause for her tense and depressed reaction finally admitted, without emotion, that her disturbance had been precipitated through worry over the health of her sister. Although such a cause, on the face of it, appeared unlikely, further information disclosed that the sister lived 3,000 miles away, had not been seen by the patient for fifteen years and was not seriously ill. Additional study revealed a far more significant factor related to this patient's illness.

Acceptance of Previously Ineffective Remedies.—Many patients with psychosomatic illness respond with satisfaction and optimism to measures of reassurance and suggestion that are unsupported by study or accurate diagnosis and that are obviously of only temporary benefit. Such hopefulness is illogical and incompatible with the previous experience of the patient who, it may turn out, has reacted to identical treatment in this same way many times before. Actually, a seemingly gullible acceptance of facile explanation, advice and treatment serves to direct attention away from the

fundamental problem of the illness, and the relief obtained may arise in part from the successful avoidance of further disturbing investigation. Similar attitudes are adopted by patients who avoid a continuation of treatment by statements of improvement or cure that are unwarranted by the facts. Thus follow-up reports of patients with psychosomatic illness are particularly subject to inaccuracy and unless conducted by physicians in local community contact with the patient can hardly be credited.

A single school teacher, aged 30, gave a history of extensive treatment for dysmenorrhea. During a period of eight years she had lost several days from work with each menstrual cycle. On some occasions partial relief had been obtained by injections of hormones. After a brief interview and scheduled premenstrual injections of sterile water, this patient reported definite improvement in her symptoms for four months. When symptoms recurred, an attempt to institute adequate medical study was met with firm opposition; the patient was intent on continuing her basically unsatisfactory pattern of palliative treatment, and was outwardly hopeful that injections would ultimately effect a cure.

COMMENT

In psychosomatic disease the physician is thus confronted with a protean and paradoxical illness, a clinical syndrome that differs from others to which he is accustomed in that the patient appears to be fundamentally indifferent to diagnosis and to treatment and on further close observation is found actually to obstruct medical study. Although the patient obviously suffers much discomfort, disability and distress from structural defect, and from a conscious rational standpoint must wish and need to recover, there are in operation powerful unconscious dynamic forces that acted to initiate or protract the illness and still function to perpetuate it. Thus the conditions and circumstances requisite to recovery and even to study of the illness are from their nature complex and obscure and rarely accessible to early disclosure or resolution. Psychosomatic disease represents a life trend in integration of personality and in intersocial adjustment; it follows conditioned patterns of physical and psychologic reaction that are not amenable to any type of management aimed at early concise analytic diagnosis or prompt correction. If the patient proposes to undertake treatment for conscious reasons that are compelling, it is clear from the foregoing observations that for equally compulsive unconscious motives such treatment must be supervised, limited, perhaps even nullified to meet the internal necessities of the person as a whole. Human behavior in illness, as in other situations, is basically *determined*, largely predicated by "feeling" and intuitiveness instead of by "pure" reason. Patients with psychosomatic illness cannot immediately undertake total remedial treatment, cannot afford to entertain seriously plans that jeopardize their protective compromise with reality and unwittingly threaten them with a more fearful danger to personality adjustment.

However, treatment of part of the illness, the local somatic end organ manifestation—for example, peptic ulcer—may be accepted when there are illness equivalents in treatment that provide substitute secondary gains, and when primary cathexes may be reallocated or displaced into other channels of physiologic (psychologic and sociologic) expression. Likewise, it must be recognized that many patients appear to give up their resistances or to succumb to cumulative pressures for study and treatment only when, through alteration of internal or external factors in the basic insecurity situation, a resolution of the total illness is impending. On

the other hand, patients who injudiciously allow external pressures to force them into premature or hasty treatment and decision may become seriously anxious and depressed unless illness equivalents have been effectively established. A physician-patient relationship may constitute such a substitution and in competent treatment should serve as a bridge to the development of other identifications compatible with reeducative goals and health.

SUMMARY

Reliable criteria for the prompt recognition of psychosomatic disease may be found among the unconsciously motivated resistance symptoms that accompany the illness and indicate its utility to the patient. These resistances, manifested by attitudes and behavior basically obstructive to medical treatment, constitute objective phenomena that serve to indicate the dynamic biologic significance of the total illness.

DERMATOLOGIC MANIFESTATIONS IN PSYCHIATRIC DISORDERS

THEODORE CORNBLEET, M.D.

and

MEYER BROWN, M.D.
Chicago

One may look at psychosomatic medicine from three different views. The first is that in which signs and symptoms in somatic organs are seen to accompany specific mental disease, such as dementia precox. This relationship is well known and accepted. An illustration is the depressed phase of manic depressive psychosis which is frequently accompanied by periodic tachycardia, amenorrhea or loss of weight. The second aspect of psychosomatic medicine suggests that specific somatic diseases are influenced by mental states. Thus, peptic ulcer is aggravated when the patient is distressed or under tension and apt to be improved during periods of physical and emotional relaxation. The third consideration is the one that is least established, but nevertheless the most discussed recently. This maintains that repeated emotional or psychologic stress may actually produce certain somatic diseases, such as asthma, essential hypertension or eczematoid dermatitis.

The present discussion will concern itself with only the first view—namely, definite mental diseases and their cutaneous accompaniments. Specifically, we wish to discuss abnormalities of the skin and its appendages which are indexes to well known psychiatric disease entities. Those dermatologic changes are not included which result from neurologic diseases, such as the excessive flow of sebum in the parkinsonian state or the trophic ulcers of syringomyelia or tabes.

DERMATOLOGIC SYMPTOMS ASSOCIATED WITH MENTAL DISORDERS

Several dermatologic symptoms are found only in the presence of mental illness. Others are nonspecific and may be met in various disease entities, physical or mental. Itching and paresthesias may be indicators of an accompanying mental disorder, though, of course,

they are most often due to primary dermatologic changes. We should suspect the possible presence of a psychiatric disorder when itching is intense, abrupt or of recent onset and not explainable or accompanied by some cutaneous change or systemic disorder. Paresthesias, however, are much more often due to psychiatric disease than is itching. They may be universally distributed, but are more commonly confined to certain portions of the skin. The most frequent sites are the scalp, face, neck, arms, hands and abdomen. These disturbed sensations are described by the patient as a feeling of numbness, tingling, burning, drawing, droplets falling on the skin, a sensation of hot or cold or of insects crawling on the skin. The chances that a mental aberration is at fault mount and increase the more intense and persistent these abnormal sensations are, providing that organic neurologic disease is excluded. A psychosis or serious mental disease is still more likely to be present when these unpleasant paresthesias are elaborate or bizarre.

Paresthesias may express themselves as unclassified unpleasant sensations of hairy parts, especially of the scalp, axilla and pubis. There may be complaints of frank pain or dermatalgia. Patients with mental disease may feel that their hair has been converted to snakes or that it seems like wood or turned to ice. Itching and paresthesias may be present in all the accessible mucosae as symptoms of mental disease. The well known burning tongue syndrome may be an example. In the same way, a raw sensation of the throat or a stinging sensation of the rectum or vagina without evidence of any local disease process or neurologic disturbance may have its basis in an abnormal mental state. In addition, these disturbed sensations cannot be accounted for by allergic or metabolic studies or tracked to any rational source. They are, moreover, accompanied by mental manifestations of the underlying neuropsychiatric disorder if one but looks for them.

Paresthesias of the Pharynx and Tongue Due to a Depression.—A 52 year old man complained of an extremely distressing "raw" feeling in the throat and the mouth and of the tongue which had lasted six months. He was seen by a general practitioner first, then in succession by a dermatologist, an otolaryngologist and finally a psychiatrist. In addition to the symptoms of the throat, mouth and tongue, the patient was found to have great nervous tension, a feeling of pressure on the head, mental depression that made him consider suicide, insomnia, anorexia and loss of his ability to enjoy previous pleasures. He avoided social activities and lost 14 pounds (6.4 Kg.) in weight. He had had a similar episode twenty-eight years before which lasted four months. A diagnosis of manic-depressive depression was made, and psychiatric treatment gave him considerable relief.

Paresthesias Due to Schizophrenia.—A woman 26 years old was seen who complained of a feeling of dryness and tingling of the skin of the trunk, axillae and groins. This had lasted for a year and was becoming worse. Many medicaments given internally or used locally, as well as roentgen rays, gave no relief. A psychiatrist found that the patient had a feeling of strong tension and irritability. The menses were scant and irregular, her appetite decreased and there was loss of weight. She had perplexed feelings about numerous things, became indifferent to her home and children and neglected her personal appearance. She had strange thoughts, such as skepticism as to whether she was really married, the identity of her children and unusual preoccupation with religion. Her husband felt she had changed a great deal during the last several months. The patient herself was unaware of these transformations, although they were obvious to her family. A diagnosis of schizophrenia was made.

Read before the Section on Dermatology and Syphilology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

From the Department of Dermatology of the University of Illinois College of Medicine and the Department of Nervous and Mental Diseases of Northwestern University Medical School.

Excessive washing or skin cleansing may be another expression of a psychiatric disorder. Such action, considerably beyond what obvious soiling can justify, should always arouse suspicion. It usually springs from fear. It may be the response to a delusional idea. The patient may, for example, believe erroneously that he will contract syphilis by contact with familiar objects, such as doorknobs, tools, eating utensils or clothing. This may cause him to wash his hands after each such contact, or he may attempt to clean or wipe these objects before touching them. He may handle objects with gloves or interpose paper or cloth to prevent contact with the bare skin. Some are fully aware of excessive hand washing and admit it readily but explain this as an irresistible impulse. They know that it is not rational. They may not rest their attempts to cleanse themselves with only soap and water but use alcohol, all manner of chemicals, or abrasives, such as sandpaper and pumice. These busied and consuming ablutionary pursuits may not be confined to the hands, but involve the scalp, the genitalia or the entire body. The presenting symptom to the dermatologist in these cases is a dermatitis of varying grades of acuity. The skin may become dried and itch as evidenced by scratching. The most common manifestation is a dermatitis with glove distribution. Simply to remember that such cutaneous changes may overlie a disordered mind proves gratifying occasionally when it helps to clarify a syndrome which would otherwise be obscure.

Excessive Hand Washing Due to Manic-Depressive Depression.—A 43 year old white man presented himself for the treatment of a dermatitis of the hands. There was a subacute dermatitis of glove distribution that included the wrists. He had been washing his hands at least fifty times a day after contact with doorknobs, tools, table surfaces or other commonplace objects. He was afraid of contamination by germs. The patient admitted being nervous for the last eight months with irritability, restlessness, unmotivated mental depression, lack of appetite, insomnia, a feeling of pressure on top of the head, tightness in the throat and the excessive use of alcohol to relieve his symptoms. He remarked spontaneously that he had lost his prior enjoyment in his work. There was a similar episode four years before that lasted two weeks, but he did not recall that he had had the same fear of contamination by germs. There was considerable symptomatic relief with psychiatric treatment.

There is a large number of persons familiar to every dermatologist who seek relief from normal or physiologic changes about which they become obsessed. This group is characterized by excessive concern over what most persons come to accept as of the normal pattern. These patients become greatly exercised by the thinning hair of middle age or even baldness, graying hair, the appearance of a few additional facial hairs, nevi, dryness of the skin or its oiliness, etc. In some cases, this concern can be rationalized on the basis of vanity, dependence of one's livelihood on a good or a youthful appearance, or marital insecurity. In spite of these plausible excuses, however, it is the excessive concern which should alert one to the possibility of an underlying neuropsychiatric disorder. This possibility becomes more probable if the alterations of the skin or of its appendages are slight or if the worry represents a change of personality pattern or interferes greatly with the patient's happiness. What is significant is the unreasonable and excessive degree of the complaint. In this same category may be included the person who reacts unreasonably to actual pathologic changes in the skin, threatening and feeling justified in suicide because a patch of psoriasis does not yield to treatment.

Excessive Concern Over Falling Hair in a Personality Disorder.—A 45 year old man was seen who complained about the excessive fall of his hair. He had been to various "institutes" and consulted various physicians as well as tried numerous preparations to combat baldness. There was a moderate thinning of the hair over the crown without accompanying seborrhea. The patient was obviously vain and overdressed and was found to be egotistic and self centered. He was expelled from two colleges. He lost several jobs and failed twice in business. His family said he was garrulous, negligent and irresponsible and could not sustain any effort. During the preceding years he did not work, while the family support came mainly from his wife's employment and that of an adolescent daughter. His loans from friends had to be repaid by his brother. He was taking increasingly to alcohol, as he said, to drown his miseries. The diagnosis was that of a personality disorder.

The antithesis to this last group of subjects is the one that is inordinately indifferent to and negligent of dermatologic disease of the kind which should call for serious attention. This may represent a trait of character and be the stoic's attitude toward his responsibilities to himself or family. If, however, such lack of concern is a change from that which was present previously, one should think of the presence of a neuropsychiatric disorder.

Epithelioma of the Lower Lip in an Indifferent Schizophrenic.—An unmarried man, 39 years old, was seen with an epithelioma of the lower lip. He had consulted with the dermatologist only after strong pressure was exerted by his mother. The patient absolutely refused to cooperate and permit any treatment of his lip lesion. He was subsequently seen by a psychiatrist who found that the man was uninterested in any work, unemployed for five years and indifferent to his self support. He had been in a hospital when he was 28 years old and was said to have had catatonic dementia precox. Six months after his release he returned unsuccessfully to his job as a machinist. He then became a stock room attendant, freight handler, janitor and lastly a night watchman. He lost each job through indifference and negligence. He was excessively religious and rarely left home. The psychiatrist found the man apathetic, responding slowly to questions, uninterested in his future and without insight into his present state. His conversation was halting, he uttered no spontaneous thoughts and some of his responses were irrelevant. A diagnosis of schizophrenia of the simplex type was made.

Dysfunction of the autonomic nervous system may give rise to dermatologic complaints, such as excessive sweating, feelings of warmth, blanching or flushing and blushing. These symptoms may be due to neurologic disease, but they frequently are part of a psychiatric syndrome. Whenever one encounters such autonomic changes referable to the skin it may prove valuable to look for the signs of a psychoneurosis or a depression or some other psychiatric disease which may underlie the patient's complaints.

Complaints based on delusional belief are always of psychiatric significance. They frequently involve the skin. Such patients entertain an opinion which is false and that no amount of evidence from any source will correct, and because of this erroneous opinion they will display unreasonable and bizarre conduct.

Delusion of Cutaneous Infestation Probably Due to Schizophrenia.—A 55 year old woman showed numerous deep excoriations and tunneling of the skin. A diagnosis of neurotic excoriations was made. She wanted relief from the bugs that were growing and living in her skin, whose movements she could feel and whose eggs she could see with the aid of a lens. She had become very nervous in the last year, lost interest in her household, husband and son. There was an unexplained feeling of nervous tension at unpredictable intervals

which was accompanied by palpitation and numbness in the head. She was seclusive from friends and relatives and bore vague feelings that neighbors considered her queer and that they gossiped about her neglected personal appearance and home. A provisional diagnosis of schizophrenia was made.

The nature of the delusion may be extremely varied. Many patients believe their skin to be infested or the seat of parasites, insects, germs or bizarre inanimate materials. They profess to feel, see and even hear them. Some believe that the skin is being transformed into leather, paper or some other nonliving material. Others with nocturnal itching or paresthesias weave and elaborate some delusional idea, which becomes a fixed belief in explanation of what is felt. It may be believed that some specific agent is acting, such as poison in food, or is contaminating the air that is breathed or is acting nefariously by means of mysterious electrical influences.

Self-induced injuries should excite interest in a patient's neuropsychiatric condition. The more obvious examples in this group are those whose injuries are gross or bizarre, such as the impulsive shearing off of the hair by a woman. A few despoil themselves for sympathy, avoidance of unpleasant responsibility, gain or other motives. They may or may not admit their guilt. The majority of the subjects in this category, however, have no apparent desire to mutilate themselves, nor do they understand the significance of their acts.

Neurotic Excoriations in a Schizophrenic.—A 19 year old boy was seen who had acne of the face, shoulders and back. There was a number of deep excoriations at these same sites which he denied making. He was apathetic and totally indifferent to the cutaneous lesions. He manipulated unaware of what he was doing. His mother said he had had a "nervous breakdown" for three months, four years before, when there were insomnia, intense agitation, hearing of strange voices, complete loss of interest in school and other activities and a delusional belief that spies were peering through the windows. Recovery was complete, but within six months there appeared a slow deterioration in the boy's ability to study. He had to leave school and gradually thereafter showed increasing loss of interest in the usual adolescent activities. He was unable to work, did not talk for periods of days, became seclusive and irritable. He sat idly for hours, while he picked at his face and gazed blankly. A diagnosis of hebephrenic type of schizophrenia was made.

Feigned Eruption Without Neuropsychiatric Disorder.—A woman, 43 years old, had a traumatic lesion of the thigh which did not heal with appropriate therapy. Nothing in a thorough examination could account for the continued presence and extension of the lesion, although there were several times when considerable improvement gave way to relapse. The patient was taken to a hospital where a cast was applied over the thigh. After three weeks, the lesion was found completely healed. A psychiatrist who visited the woman at the hospital found no basis for a diagnosis of any psychiatric disorder but called attention to the fact that her lesion made it possible for her to receive workman's compensation.

Pulling of Cuticle and Nail Biting in a Neurosis.—An Italian woman, 32 years old, complained of soreness of her finger tips. There were several paronychias, the periungual tissues were traumatized and the nails short and irregular. She admitted that she was preoccupied with biting her nails and pulling the cuticles and that this had been going on for several months. The patient said that she was doing this because of her nervousness, which was brought about by her troubles. These were moving into her father-in-law's because of poor economic conditions and constant family bickering. She experienced again her old "stomach trouble," which was a feeling of bloating, fatigability, increased irritability and sensitiveness. She had no depression or derogatory ideas or inability to enjoy her usual pleasures. She could not fall asleep, but her appetite

and weight were unchanged. There were spells of heavy breathing and faintness after her many arguments. A diagnosis of psychoneurosis was made, and improvement followed psychiatric treatment.

COMMON PSYCHIATRIC DISORDERS ASSOCIATED WITH DERMATOLOGIC SYMPTOMS

Instead of considering the bald symptoms themselves, it may be worth while to give some thumb nail sketches of psychiatric entities often associated with dermatologic complaints. Many other mental disorders not described here may have cutaneous components. In this incomplete recital, we shall limit ourselves to a discussion of only four of the most common psychiatric states.

Perhaps in schizophrenia or dementia precox, more so than in any other psychiatric disease, the patient is apt to consult the dermatologist early. He seeks advice about some cutaneous sign or symptom long before the need for psychiatric attention is obvious to either the patient or his family. In dementia precox, the patient is particularly apt to develop delusional ideas referable to his skin or its appendages. The delusional belief may be that the patient is infested with parasites or that his skin has been tanned to leather. Endless variations of such complaints may be encountered. These and others of their kind should arouse suspicion that the patient may have schizophrenia. Persons with self-induced lesions should likewise be suspected, especially those who do not appreciate their own guilt or the extent of their inflictions. They may pull wads of hair from the scalp, gouge the skin or busy themselves with endless picking, scraping, scratching or cutting of the skin. This may result in far flung infection, denudation, tunneling or canalizing not only the skin but of the accessible mucosae as well. The hair may be disturbed in diverse ways and the nails mutilated. Bizarre paresthesias may indicate an early schizophrenia. There may be the sensation of ants scurrying over the surface of the skin or insects titillating some particular site. There may be the feeling of touching ice or the fall of drops on the skin or a sensation of being constricted. In addition to these symptoms many patients will show an unusual preoccupation over normal physiologic changes of the skin and hair.

Trichotillomania Due to Schizophrenia.—A 10 year old white girl was seen in the dermatology clinic for loss of hair. There was a partial alopecia over the crown, which extended forward to the anterior hair line. A diagnosis of trichotillomania was made. During the interview with the mother, the patient was seen to twist and turn her hair, apparently unaware as she gazed blankly in the distance. The mother had noticed a slow progressive change in the child's personality during the preceding two years. There were irritability, sensitivity and loss of interest in the usual activity of children. She preferred to sit alone, mute for extended periods, and showed impulsive cruelty to a younger sister. She laughed or cried on little provocation, was markedly apprehensive and showed no understanding of her change in reaction to school, her parents or playmates. The patient vigorously denied that she herself was guilty of pulling out her hair.

The course and symptoms of schizophrenia are extremely varied, and a listing of them is difficult to compress into a small space. The disease appears in childhood or adolescence in many cases and is usually progressive. It persists for years or decades with fluctuation in its intensity and extensiveness of its symptoms. It tends toward progressive deterioration and ultimate mental incapacity. Early in its course there may be an unreasonable and exaggerated irritability and irascibility with outbursts of temper on slight

provocation. Often there may be impulsive speech and action inappropriate to the circumstances. The commonest symptom is an insidious progressive loss of practical efficiency. The patient makes an increasing number of errors, is neglectful and shows less responsibility. There is apathy and indifference to persons and interests with which the patient was previously occupied. Frequently there develops a feeling of nervous tension or uneasiness, inability to concentrate, depression or apprehension. Delusions and hallucinations are characteristic of schizophrenia, though they are not constant. There are bizarre habits of conduct, asocial and antisocial tendencies, laughing and crying on little or no provocation and refusal to speak for hours. There are perplexed and disordered mental processes about such familiar subjects as family affairs. Insomnia develops. The subject frequently loses much weight, has amenorrhea, unexplained cold, cyanotic fingers and toes and other physical changes. Often there is a total lack of insight into or awareness of the presence of these grave and numerous mental and physical changes. The cause of this disease is unknown, though there is no dearth of theories.

In the depressed phase of manic-depressive psychosis there are itching and paresthesias of the skin and mucous membranes and excessive concern over physiologic changes, such as falling hair or changes of pigmentation. Autonomic disturbances referable to the skin occur frequently, and dermatitis may be induced by excessive cleansing, but, in general, delusions about the skin or its appendages occur infrequently. The depressed phase commonly referred to as a "depression" or "melancholia" is relatively common. This may be mild enough to escape notice or severe to the degree that requires institutional care. This syndrome tends to have a familial incidence, though its cause is unknown.

Manic-Depressive Depression Producing Excessive Concern About the Texture of Skin Over the Face.—A 20 year old unmarried woman complained of nervousness, which a gynecologist did not relieve by the administration of hormones. She was depressed, lost interest in recreation, suffered periods of panic with dread of impending disaster, became fatigued easily and slept poorly. She had lost 15 pounds (6.8 Kg.) in weight, was markedly critical of herself and was obsessed that her face, as she said, "looked awful." She made much about her skin, which she believed coarse and pasty. This concerned her so deeply that she withdrew from and shunned all company. No precipitate stress could be found for her illness. This improved after three months of psychiatric treatment but recurred in a milder form six months later.

Its episodic character is the outstanding feature about manic-depressive psychosis. These attacks may last for only a few days or last throughout a number of years. There may be dozens of the attacks or only one. Remissions occur in every case and are nearly always complete, though they may last only several hours or extend for the duration of the patient's life. The most important symptom is mental depression or sadness which cannot be justified by external circumstances. There are many other physical and mental symptoms, such as excessive fatigability, insomnia and loss of appetite and weight, as well as a distressed feeling in the head, chest, abdomen and extremities. Mental symptoms are invariably present but are often not mentioned spontaneously and consequently are often overlooked. The patient no longer enjoys what were formerly pleasures, such as friends, food, music or some hobby. Loss of initiative accompanies this lessened interest in usual pursuits. These patients disparage themselves

and their ability, feel inadequate or helpless and believe that they are despicable and worthless. They are distressed with baseless fears of impending insanity, brain tumors, cancer, syphilis or heart disease. There are episodes of panic about nameless impending disasters. There are excessive irritability and sensitiveness and poor powers of concentration. Unprovoked crying spells are exceedingly common. There is complete insight and cruel awareness of their symptoms and disability in contrast to what is found in schizophrenia. These patients suffer intensely and are eager to cooperate to relieve themselves.

A psychoneurosis is less apt to have a cutaneous presenting symptom though it is a common psychiatric disease. Autonomic phenomena in the skin, such as excessive sweating and flushing, are frequently part of a psychoneurosis. Occasionally there is itching, but paresthesias, such as tingling, numbness or the feeling of coldness, are commoner. Excessive cleansing is seen less frequently than in manic-depressive psychosis or in schizophrenia but excessive concern over physiologic changes is seen more frequently, as well as self-induced injuries, especially of a minor character. There is picking of cuticles, biting of nails and excessive squeezing of blackheads.

Excessive Concern Over Sagging Skin About the Face Due to a Psychoneurosis.—A 46 year old woman said she had "gone to pieces" during the last six months coincident with being abandoned by her husband, to whom she was devoted and married eighteen years. She had insomnia, anorexia, weeping spells, tremulousness, irritability, fatigability, a clutching sensation in the throat, a feeling of crushing pressure on the head and frequency of urination and lack of ability to concentrate. Her most distressing thought was concerned with a fixation about the sagging, redundant skin of her face, which she felt was partly responsible for the husband's defection. She tried many kinds of lotions and went to several dermatologists, all of whom minimized her complaints and just dismissed her.

A psychoneurosis, or, more simply, neurosis, is a specific mental disorder induced by intolerable mental stress. The factors setting up these strains may be economic want, fear of illness, marital unhappiness, overwork or others. The intensity of the physical and mental symptoms parallels that of the induced emotional turmoil. These symptoms include fatigability and physical distress without organic changes, irritability, restlessness, sensitiveness, emotional upheavals accompanied by insomnia and complaints about tremulousness, excessive perspiration, tachycardia, light-headedness or other "functional complaints."

Those with personality disorders constitute the fourth and last of the large groups of patients with mental disorders that frequently present cutaneous symptoms. Itching often is severe but paresthesias and excessive washing occur less commonly. Exaggerated concern over physiologic changes of the skin and hair are seen frequently in this group. There are never delusions about the skin, but, as in the psychoneuroses, there may be self-induced injuries and autonomic changes. It is in this group with personality disorders that self-induced injuries are found very frequently.

Itching Due to a Personality Disorder.—A 21 year old young woman complained of intense pruritus about the vulva, anus and thighs. A thorough physical examination disclosed no abnormalities. She appeared to be uncomfortably tense and said that itching was exacerbated during periods of maladjustment. All her life she had been considered unstable emotionally, selfish, irresponsible, without perseverance and inadaptability. She was constantly in difficulty in schools, three of which she left

under duress. She abandoned her parents' home several times, was ejected twice from that of her brothers and four times attempted unsuccessfully to live with friends. She held six different jobs in four years, during which she went on numerous periods of idleness. The patient impulsively broke three engagements to marry and said that she simply did not belong anywhere. Each exacerbation of pruritus occurred with a new conflict, such as discharge from a job, ejection from her brother's home, breaking an engagement or an argument with her father.

The characteristics of this group are so varied as to make impossible their compression into a small space. These subjects have character traits which from childhood set them off as different from the accepted and normal pattern. These lead them to maladjustment and include emotional instability, deceitfulness, laziness, dishonesty, irresponsibility, lack of initiative, perseverance and adaptability, cruelty and selfishness. Because of such personality traits these persons are chronic burdens and nuisances to their friends and families. There are repeated transgressions of accepted conduct at school, work, or home or in the military service. This disorder may lead to alcoholism, delinquency or addiction to drugs.

COMMENT

These brief outlines of four common psychiatric diseases are not intended to enable the practitioner to make final diagnoses. He may, however, become more conscious of their presence in his patients, who otherwise are merely nuisances or have some sign or symptom for which he knows no convenient classification. His suspicion may be aroused by unusual changes in the skin, but he may confirm his feelings by a few adroit questions that reveal symptoms referable to the nervous system. It may be found that there are such characteristic symptoms as insomnia, mental depression, excessive fatigability, irritability, sensitiveness, periods of nervous tension and specific fears. The examiner may notice the patient's apathy, the latter's emotional tension or lack of insight. A few questions about the patient's record at school, at work, or in the home may point up a marked deviation from previous habits, conduct or attitudes or his poor adjustment during most of his life. The physician other than the psychiatrist, of course, cannot appreciate the full significance of the information which he has thus elicited, but he can better understand thereby the need which his patient may have for the psychiatrist's evaluation and treatment. Such therapy administered early is apt to be more successful, saves the physician face and unpleasant labor and the patient much distress.

It may not be amiss to repeat and list a few of the indexes that have been detailed:

Recapitulation of Dermatologic Indexes to Neuropsychiatric Disorders

1. Itching and paresthesias
2. Excessive washing
3. Excessive concern over physiologic cutaneous changes
4. Inordinate indifference toward and negligence of serious disorders of the skin
5. Autonomic cutaneous disturbances
6. Delusional beliefs about the skin
7. Self-induced injuries to the skin, feigned or admitted

Recapitulation of Indexes Suggestive to Psychiatric Disease

1. Marked deviation from previous habits, enjoyments, conduct or attitudes
2. Fatigability and insomnia
3. Exaggerated irritability
4. Impulsive speech and action
5. Loss of efficiency
6. Apathy and indifference
7. Marked nervous tension
8. Depression or vague apprehension
9. Delusions and hallucinations
10. Delusions and crying without provocation
11. Lack of insight
12. Loss of appetite and weight
13. Emotional excesses
14. Maladjustment to environment, chronic or recent.

The four psychiatric diseases which have been outlined appear to overlap considerably, with many symptoms, such as insomnia, common to all of them. There are, nevertheless, critical differences that indicate that they are separate disease entities. Psychoneurosis is an illness which results from inability to cope with emotional strain, but schizophrenia, manic-depressive depression and personality disorder are probably independent of environmental influences. Insight into and comprehension of the extent and significance of symptoms are almost always absent in schizophrenia and almost always present in the others. Personality disorder shows abnormalities throughout the lifetime of the patient, whereas in the other diseases he may be normal for many years prior and subsequent to the time of sickness. Manic-depressive psychosis is characterized by a remitting episodic course, whereas the others are less apt to show recurring attacks of the same illness.

SUMMARY

Certain symptoms and signs of the skin and its appendages, as well as the accessible mucosae, often are indicative of an underlying psychiatric disease. There is a brief description of four common psychiatric disorders in which cutaneous changes occur. Guideposts are suggested in the examination of the patient for the recognition of psychiatric disease. It is emphasized that earlier detection of an underlying mental illness improves therapeutic results and avoids prolonged misinterpretation and suffering.

ABSTRACT OF DISCUSSION

DR. MARION B. SULZBERGER, New York: When asked to discuss this paper I feared that I would be asked to say something about psychosomatic influences in dermatology. It was a relief on reading the paper to find that the authors had gotten away from the morass of conjecture, emotional bias and post hoc reasoning, and the interpretation of possible coincidences as being proved to be in unequivocal relationships of cause and effect. The tendency to regard what may be coincidence as proved causal relationship has been one of the great difficulties in the psychosomatic field. Dermatologists have seen many remarkable examples of the almost unbelievable coincidences. To illustrate I will tell you an account related to me yesterday by a young lady employed by a large medical publishing house. She was recently engaged in reading proof on a textbook on dermatology. Apparently it was a good book, because when she came to read proof on the sections dealing with bedbugs she began to suffer from manifestations similar to those described as caused by bedbug bites. She searched her home, and found that there really were bedbugs there. Later she came to the section of the text devoted to pediculosis pubis, and began to feel again the characteristic results of the infestation described. Even more strange to relate, on examination it was discovered that she had actually acquired the described pediculosis. Now how should this sequence be interpreted? Is it an example of psychokinetic effect (in which thoughts make matter take on certain forms and arrangements), combined with parthenogenesis (because in this case the matter also became alive)? Or was it merely an example of strange coincidences? One of the dangers in the present attitude of many physicians toward psychosomatic concepts is that they have found that by adopting this school of thought they need have no more therapeutic failures. This is convenient approach for the overbusy physician, who may often be tempted to say that those cases which defy causal diagnosis and which resist orthodox medication are, by exclusion, psychogenic. Moreover, this easy solution is made easier by the public's present maleducation on "psychosomatics" and because many patients like to think of themselves as being highstrung and very tense and nervous. All life is a series of emotional changes, so that he who wishes to can almost always find some relationship in time between the appearance and disappearance

of any symptoms and the appearance and disappearance of emotional strains. I enjoyed this presentation particularly because no conclusions have been drawn on the basis of purely chronological relationships.

DR. FRANCIS W. LYNCH, St. Paul: The authors' purpose was to aid in earlier diagnosis and, therefore, earlier institution of treatment of psychotic states by recognition of the dermatologic indexes which they have listed. In my opinion, after recognition of a psychosis the patient should seldom be treated further by the dermatologist but rather by the psychiatrist. Therefore, this group of dermatologic patients is of less concern to the nonpsychiatrist than is the group in which there is more somatic reaction to psychic influences; for example, in eczema and other neurodermatoses. In all these states the dermatologist is in need of greater neuropsychiatric diagnostic and therapeutic ability. This paper is one step in advancing our knowledge. Continued studies should produce evidence that certain dermatoses are constantly associated with certain specific personality traits of a neurotic nature. Possibly also certain sites are specifically related with the neurotic traits. Already there is some evidence for such an association in eczema, psoriasis and the seborrheic states. After hearing this paper, I am not sure of the author's views as to the specificity of the psychiatric relationship to single or multiple dermatologic indexes in their list. I will appreciate an expression of their opinion on this point, and also regarding the frequency with which the various dermatologic indexes occur in psychotic persons of the four groups which they have considered. Without some such figures, I hesitate to accept their statement that the psychoneurotic person is "less apt than the psychotic to have a cutaneous presenting symptom." The skin is a common site of reaction to normal and abnormal psychologic and emotional influences. Like Dr. Sulzberger, I would be pleased if we had more accurate measures with which to work. There are numerous reasons why we do not, but I am unlike him in that I am much more encouraged and hopeful for the future and believe that much yet will be learned in the field of investigations of personality.

DR. ADRIAN H. SCOLTEN, Portland, Maine: What shall be done about these dermatologic patients recognized as having some mild psychoneurosis and who are not getting needed spiritual help? The treatment will never be easy. It will take time to get the training which is needed to have a worth while understanding of the psychoneurotic person's problems which we meet in our dermatologic practice. The psychoneurotic person is a supersensitive, intelligent being who lives inefficiently. If we who wish to help him would put ourselves in his place and handle his problems as we would handle them if they were our own, we would then give to him the more balanced judgment which he needs. Statistics show that one third of all the patients who come to the dermatologists' office are psychoneurotic. Therefore, we should be treating their psychoneuroses as well as their dermatologic conditions. In our generation there will never be enough well trained psychiatrists to handle so many psychoneurotic persons. Most good psychiatrists believe that only a small percentage of those who have psychoneurosis need psychiatric or other profound treatment such as only a psychiatrist can give. They believe, as I do, that the old-fashioned family doctor practiced a good brand of psychiatry. He knew all about his patients; he knew how to handle the family's domestic and psychiatric problem, and he kept many of his patients from developing psychoneurosis and he also kept many of them out of the institutions for the insane. This type of technic is one which dermatologists can learn. Much could be learned in one-month courses given by the right men. The physician treating the psychoneurotic patient must be sincerely interested in his patient's welfare. The dermatologist who is as interested in his patient's family and other problems as was the old-fashioned family doctor will get some satisfying results. The priests, the ministers, the teachers and the friends of the patients are aids which every dermatologist can use to good advantage in his handling of dermatologic cases with psychiatric or psychogenic or emotional components. These persons, though not physicians, often give to psychoneurotic persons the certainties which they have lost. They preach to them the gospel

of acceptance and balanced living. They give them needed security and freedom from foolish fears. In the successful practice of dermatology, psychiatry and dermatology must travel hand in hand.

DR. MEYER BROWN, Chicago: As far as the questions that were raised by Dr. Lynch are concerned, I first would like to point out that in dermatology as well as in psychiatry there is difference of opinion as to classification of disease entities. Patients with psychoneuroses show dermatologic complaints less frequently than patients with schizophrenia or manic-depressive psychosis in my experience. As a matter of fact, the great majority of the dermatologic complaints that occur in psychoses never even come to the attention of the dermatologist, because the psychiatric state has become so obvious and severe that the dermatologic change becomes of secondary importance. A patient, for example, who believes that his wife is attempting to poison him by putting arsenic into his food is not likely to come to a dermatologist after he has been in an institution for a year or two, because he erroneously thinks the arsenic is finally producing some dermatologic symptoms. We had hoped merely to call your attention to the fact that dermatologic complaints are frequently the initial manifestations of a psychiatric state and that you owe it to yourselves as well as the patients to keep that in mind.

HOOKWORM INFECTIONS IN AMERICAN SERVICEMEN

With Reference to the Establishment of *Ancylostoma Duodenale* in the Southern United States

ELMER H. LOUGHLIN, M.D.
Brooklyn

and

NORMAN R. STOLL, Sc.D.
Princeton, N. J.

One of the helminthologic features of World War II was the exposure of servicemen to infection with hookworm in areas infested with *Ancylostoma duodenale*, particularly in the Pacific islands. Reports of studies confirming this are gradually accumulating. The information available to date, together with certain emphases arising from a further examination of data secured by us on navy and marine personnel while on Guam, are brought together here to determine their relation to the question of the potential establishment of *A. duodenale* in the United States.

REVIEW OF PREVIOUS REPORTS

That *A. duodenale* was endemic in many of the Pacific islands, its amount increasing in relation to *Necator americanus* as the mainland of Asia was approached, has been recognized for many years. There may, however, be considerably more *A. duodenale* in some areas than hitherto has been realized. The rate of infection with *A. duodenale* in troops who have been engaged in combat and of course have been exposed to hookworm infection, as well as in natives in these areas, gives one index as to the endemic intensity of this species. Liebow and Hannum¹ reported only *A. duodenale* recovered after treatment from 10 ser-

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

vicemen who fought in the Solomons. Stoll² showed it to be the predominant hookworm species in natives of Guam, although the minor form in natives of Okinawa. He also found *A. duodenale* to an appreciable degree in marines returned from Leyte.

Australian soldiers who fought on the islands north of Australia were the first to be reported³ as having contracted hookworm infection in this area; about a third of those with hookworm infection harbored *Ancylostoma*.⁴ Sangster⁵ found that hookworm infection among "Australian army personnel increased steadily since the early days of the New Guinea campaign in 1942." In nine months at Port Moresby in 1943-1944 his cases were only *Necator* infections, while in Bougainville, January to June 1945, both *Ancylostoma* and *Necator* were contracted. One patient, in the latter group, was proved by post-treatment examinations to have been infected with approximately 3,500 hookworms.

Not all the reports on hookworm infections in American servicemen have disclosed the particular species present or the relation of incidence of infection to clearly defined exposure. Michael⁶ in a study of 1,000 patients who had returned recently from Pacific naval duty found only 3.8 per cent with hookworm, while in a group of 1,000 repatriated prisoners of war 15.9 per cent were infected. His use of sugar flotation for diagnosis, in place of salt, may account partly for these low figures. Markell,⁷ at a naval hospital in New Zealand, examined by zinc sulfate flotation the feces of 1,371 patients, mostly navy and marine personnel who had come from various parts of the South Pacific, and found 8.5 per cent to have hookworm infection, including men from Northern states. Zarrow and Rifkin⁸ over a two year period, in a general hospital in the South Pacific, examined by zinc sulfate flotation 3,415 soldier inpatients with service "up to three years in the various islands in the South Pacific area," and found 13.2 per cent with hookworm infection. They noted hookworm infections as frequent in soldiers from Northern states as from Southern states, but gave no data on this point.

The incidences of infection are higher with more clearly defined exposure. In a paper entitled "The influence of Combat on the Incidence of Intestinal Parasites," Russell, Eisenhower and Roose,⁹ at a Pacific base, reported the difference in incidence of hookworm infection in three groups of 100 men each as determined by zinc sulfate and brine flotation: A replacement group, which had just arrived from the continental United States, included 6 men with hookworm infection; a second group, stationed at an advanced base

but with no combat duty, had 4 with hookworm infection, and a third group, which had been subjected to combat conditions, had 25 with hookworm infection. At a base hospital in the South Pacific in August 1943, Allen¹⁰ found 28 of 71 men from the Solomon campaign to have hookworm infection, and Liebow and Hannum,¹¹ examining men in 1943-1944 on rest and retraining after service in Guadalcanal and New Georgia, encountered high eosinophil counts and about 25 per cent infected with hookworm. Recently, May,¹² at Bruns General Hospital, Santa Fe, reported that 35 per cent of 400 soldiers interned by the Japanese after the fall of Bataan were shown by zinc sulfate flotation to have hookworm infection. In only two of these studies, that of Liebow and Hannum¹ (on 10 men) and that of Zarrow and Rifkin⁸ (on 3 men), was the species of hookworm determined. These investigators found only *A. duodenale*, and did not find *Necator*. It seems doubtful to conclude, however, that all infections contracted in their areas were exclusively of this species.

Three other studies throw more light on the *Ancylostoma* index in American servicemen who had Pacific duty. Of 2,500 consecutive patients admitted from the Pacific area, examined by Most, Hayman and Wilson¹² at Moore General Hospital, Swannanoa, N. C., with several techniques including zinc sulfate and brine flotation, 11.5 per cent were found to have hookworms, whereas 6.2 per cent of 4,300 patients with service only in continental United States had hookworms. Most and colleagues stated that "the composition of both groups from the standpoint of residence in Southern hookworm states is sufficiently uniform so that this factor is not responsible for the difference observed." In a group of 169 men returned from the Pacific area and found to have hookworm infection, whose worms were recovered after treatment for the purpose of determining species, 100 had *A. duodenale*. If this ratio were extended to the 11.5 per cent incidence of hookworm infection in men who had had Pacific duty, then 6.8 per cent (or 1 in 15 men) brought back *Ancylostoma*.

In the survey made on Guam,¹³ it was found that 16.3 per cent of 1,983 men from eight military organizations had hookworm infection when examined by Lane's direct centrifugal flotation. Of these 1,241 were garrison force personnel who had never had combat duty and had not arrived on Guam until the island had been secured; the remaining 742 were marines from a heavy artillery battalion who had been brought from the Leyte campaign to Guam for rest and retraining. All were examined on a fair sample basis five to nine months after their arrival on Guam. Of the garrison force personnel, 5.7 per cent had hookworm infection; of the marines returned from Leyte, 34.1 per cent.

To carry the analysis further, data were obtained from the personnel records and the percentage of those infected correlated with three factors: age, period in service and home states. Taking the groups as a whole, in neither garrison force personnel nor marines returned from Leyte were there striking differences

in the percentage infected with regard to age or period in service; however, there was a clear correlation with home states. Of garrison force personnel whose homes were in the Southern coastal states (Virginia, North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi and Louisiana), 20.8 per cent were infected as contrasted to less than 5 per cent from other Southern states and less than 3 per cent from Northern and Western states. On the other hand, of the marines returned from Leyte, 48 per cent from the Southern coastal states, 38 per cent from other Southern states and 31 per cent from Northern and Western states were found to be infected with hookworm. It is of interest that these three percentages become 27, 33 and 29 when the respective geographic incidences of the garrison force personnel are subtracted, indicating that although the series was small, there was, regardless of home state, substantial similarity in the rate of contraction of infection on Leyte. This accords with expectation.

It was further shown by Stoll² that of those who were infected with hookworm and whose worm species were determined, about 3 in 8 of the Guam garrison force personnel had *Ancylostoma*, whereas 7 out of 8 of the marines harbored this form.

Rephrased not in terms of those found to be infected with hookworm but in terms of all examined, our figures showed *Ancylostoma* to be present in about 2 of each 100 men of the garrison force personnel and in 30 of each 100 marines who had participated in the Leyte operation. These figures are not at variance with the data of Most and co-workers,¹² at the Moore General Hospital, who found approximately 7 in 100 men returned from the Pacific, but not classified as to participation in combat, to have *Ancylostoma*. If it is assumed that the men consecutively admitted to Moore General Hospital from the Pacific were in the ratio of about 1 combat to 5 garrison force personnel, with exposures to hookworm similar to that of our two groups studied on Guam, then *Ancylostoma*-infected persons would appear in the ratio of about 7 in 100 men returned from the Pacific.

In addition to the Pacific theater, *A. duodenale* has been reported by Rogers and Dammin¹⁴ in American troops in Assam and Burma. They stated: "We have no reliable data on the actual incidence of hookworm infection among the troops who served in the forward areas, but it must have been considerable." Of 14 of their patients, the worms from whom were counted after treatment, *A. duodenale* was found in 12.

Summary of Reports.—From the studies reviewed it is apparent that hookworm infection was demonstrable to an appreciable degree in American servicemen who had Pacific duty,¹⁵ as was also the case in Australians.¹⁶ However, in evaluating the percentage of those who became infected in the Pacific, it is necessary to take into account that men who did not leave the continental United States or who had recently left and had not participated in combat showed some infections,¹⁷ especially those from the Southern coastal states.¹³ It was also shown anew that the species *A. duodenale* was present on islands of the South and West Pacific

area,¹⁸ and was demonstrable in Americans after service in the Pacific area.¹⁹ Finally, it is possible to express to a certain degree the extent to which *Ancylostoma* was a component of the hookworms acquired. Phrased in terms of 100 men examined on a fair sample basis after Pacific duty, *Ancylostoma* was present in 2 of 100 men of the garrison forces on Guam,²⁰ 7 of 100 with Pacific duty but with garrison and combat service not differentiated,¹² and 30 in 100 of the marines returned from Leyte.²⁰

In instances in which egg or worm counts were made, the hookworm infections were found to be usually light, although not exclusively so.²¹ Post-treatment worm counts of infected persons to determine species of hookworm present revealed in three reports the following numbers of *A. duodenale*: a total of 886 from 10 soldiers¹; from 1 to 112, averaging about 10, in 100 cases in an army hospital,¹² and from 1 to 107, averaging about 17, in 20 cases in navy and marine personnel.¹³ *A. duodenale* was also contracted by American troops in Assam and Burma.¹⁴

In any evaluation of intensity of infection with *A. duodenale* on the basis of worm counts, it should be remembered that this species lays two to four times as many eggs per day as does *N. americanus*.²²

ADDITIONAL CONSIDERATIONS BEARING ON POTENTIAL ESTABLISHMENT OF *A. DUODENALE* IN THE SOUTH

The implications of these data, showing that a component of *A. duodenale* was brought back to the states by one out of 15 men with Pacific duty, or approximately 7 per cent, are apparent when it is realized that most of the men who returned home from the Pacific never had a fecal diagnosis and consequently, if infected, were never treated.²³ Considering the fact that the majority of infections were nonsymptomatic, their recognition and treatment before discharge would have been a lucky accident. Although some difficulty was encountered in removing the last of the *Ancylostoma*, even by repeated treatment,²⁴ which our experience confirms, nevertheless treatment, when undertaken, reduced the number of worms and diminished the chance for the spread of infection.

From the point of view of our present interest, men returning with nonsymptomatic infections to homes in those states which have no hookworm problem can be forgotten, since unfavorable climatic conditions as well as other factors will cut off reinfections and the worms will eventually disappear. The statistically small chance that an occasional *Ancylostoma* carrier residing in the Northern or Western states will establish soil infections on some trip to the South can be dismissed for practical purposes.

Potentialities for establishing *Ancylostoma* in the South, particularly in the coastal states, lie with Southern exservicemen who returned to their homes from

Pacific duty. What can be expected regarding their habits in relation to hookworm infection? It seems to us a clue to this appears in a reanalysis of our data on the examination of garrison force personnel on Guam. These 1,241 men, 98 per cent of them white, came from

that of the men worms from whom were counted after treatment two thirds had pure *Necator* infections, when the preponderant species on Guam was *Ancylostoma*.¹³

In table 1 the data on the examinations of the Guam garrison force personnel are shown simultaneously in

* Of 742 men examined, 34.1 per cent had hookworm infection; of a sample group of infected men, whose worms were collected after treatment to determine species, *A. duodenale* was present at the rate of 7 in 8 infected men, or 30 per hundred of 742 men.

† Southern coastal states: Virginia, North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi and Louisiana.

‡ Other Southern states: Texas, Oklahoma, Arkansas, Missouri, Tennessee, Kentucky, West Virginia and Maryland.

The table includes the results covering 725 of the 742 marines examined and previously reported in less detail¹³; for 17 (including 3 infected men) data were incomplete as to home state, age or period in service. All these marines except 2 had been in service more than twelve months. The average age of all marines examined was 22.6 years.

five organizations which had been on Guam five to nine months, and showed an incidence of 5.7 per cent hookworm infection. It was concluded that these represented primarily hookworm infections contracted in the United States, as evidenced by their history, the heavier rate in men from Southern coastal states and the fact

relation to age groups and period in service of men for each group of states. In the men from Northern and Western states, who constituted over half the series, it will be noted that the hookworm infection rates were low, had little relation to age but increased with period in service, none in their first year being positive.

These infections were, without doubt, all contracted in service, perhaps some in Southern camps and, certainly, in view of the *Ancylostoma* component as noted elsewhere, some in the Pacific.²⁵ The situation with regard to men from Southern coastal states is the opposite. Even with the small numbers examined, there is infection present in their first year of service and there is a 25 per cent incidence in the 20 to 29 year age group. The data in table 1 on men from "other Southern States" show intermediate indexes.

The age incidences in men from Southern coastal states resemble those given by Keller, Leathers and Densen²⁶ in their over-all analysis of surveys of rural whites in six Southern states (North Carolina, South Carolina, Florida, Mississippi, Tennessee and Kentucky). Our data did not include information on rural and urban residence. It seems likely that if they had, the rates for men from rural areas would have been higher. If we subtract the rates of infection of men from the Northern and Western states, which represent infections not acquired in home states, from the rates for men from the Southern coastal states, the balance, 18.1 per cent, may be taken to represent infections acquired before entering the service.

This percentage of infection acquired before induction permits of two explanations: The data for the age groups 18 to 29 presented here indicates either that these hookworms were acquired in earlier life and persisted in significant numbers or that hookworms were being acquired shortly before induction into service. It seems to us that the former could account for no more than a fraction of the infections encountered in these surveys. Data are still fragmentary as to the length of life of undisturbed hookworm infections. In one study²⁷ of four experimental *Necator* infections showing initially 270 to 470 eggs per gram, two showed no drop in egg count after three and one-half years, but the other two were detectable only by flotation after one year and one and one-half years respectively. Of the 37 men with hookworm infection represented in the Southern coastal states (table 1), 31 were found on dilution count to average 1,650 eggs per gram (range 100 to 6,100). If we believe that the infections in this group of men included those acquired shortly before entering service, thus being due to a continuation through adolescence of faulty hygienic habits, it would then seem reasonable to suppose that those men from the Southern coastal states would persist in habits favorable to the establishment of *Ancylostoma* on returning home.

This same reasoning would apply to the *Ancylostoma*-infected marines from the Southern coastal states, and for comparison there is included table 2 showing the results of the examination of 725 of 742 marines returned from combat service in Leyte for whom information is complete as to home, state, age and period in service. Distribution of the infection in relation to the three factors is apparent, especially when the data are considered in comparison with table 1.

Although we have not touched on the bionomics of *A. duodenale* in relation to its gaining or maintaining a foothold in the Southern areas, the epidemiologic

implications are, nevertheless, clear. The observations of McCoy²³ are therefore worth bearing in mind:

Ancylostoma presents a greater public health problem than *Necator americanus*, the species now established in the southern United States, because it is more harmful to the host, is less amenable to treatment, and because its free-living stages are more resistant to climatic conditions.

SUMMARY AND CONCLUSIONS

We have presented epidemiologic data concerning the probable establishment of *A. duodenale* in the Southern United States. Of servicemen returning from the Pacific 1 in 15 has been reported infected with this species of hookworm. Also, analysis of hookworm infections carried by American servicemen from the South suggests the continuation into young adulthood (18 to 29 years) of faulty hygienic habits acquired in childhood. The presence in returnees of these ages of a measurable incidence of *A. duodenale* is thus combined with the evident persistence of practices favorable for dissemination of hookworms. The suspicion is thus increased that *A. duodenale* has an opportunity to appear in areas of current hookworm infection. Confirmation of such suspicion must await discovery of the first instance of proved autochthonous infection, probably in one of the Southern coastal states.

ABSTRACT OF DISCUSSION

DR. HAROLD B. WOOD, Harrisburg, Pa.: *Ancylostoma duodenale* has long been known to be in the Pacific islands, and for many years has occasionally been found in our Southern states. From Dr. Loughlin's statement we are led to believe that our servicemen contracted the *Necator* infestation in these islands. The *Necator* was discovered in our South and for many years was believed to be indigenous there. I should like to ask whether examinations were made of the natives on the islands when our medical service first arrived, to determine the danger of our troops' contracting the disease from the natives. I am sure that the International Health Board of the Rockefeller Foundation would appreciate a reprint of this paper by Drs. Loughlin and Stoll. An important result of a paper like this is to develop the attitude of surgeons toward these troops, particularly those who do not say where they have been.

DR. NORMAN R. STOLL, Princeton, N. J.: The interesting thing about the epidemiology which Dr. Loughlin has presented is that all that we can do, on the basis of present information, is to increase our suspicion as to the probable establishment of *Ancylostoma duodenale*. We speak of *Necator americanus* as our so-called American hookworm. Originally it was an African form, and it now extends in a broad belt throughout the equatorial regions. While the old world hookworm, *Ancylostoma*, overlaps the endemic *Necator* areas, it appears to do better where climate is somewhat more temperate. We have not dwelt on the biology of *Ancylostoma* in this epidemiologic report, but its consideration suggests that *Ancylostoma* may have a good chance as a species in our own Southern states. It is a form which is favored by environmental factors of the sort which we have there. A priori it should get along better than *Necator*, which has stood the South so well. These points should be kept in mind as we wait for the first report of the finding of autochthonous *Ancylostoma*. Also we should remember that *Ancylostoma* is considered a more damaging pathogen than *Necator* and less subject to satisfactory treatment. May I add that searching for *Ancylostoma* after treatment need not be considered such an unpleasant adventure as is sometimes thought. To post-treatment stools add a large volume of water or half-normal saline solution, allow several minutes for it to sediment, and cautiously discard the supernate. Continue such washing to secure a clean sediment. The worms, if present, may then be readily discovered by examination of the sediment in small amounts in shallow dishes, against a dark background. Screening the diluted specimen through a mesh of 60 to the inch or finer may be used to speed up the process.

ANASTOMOSIS OF VAS DEFERENS AFTER PURPOSEFUL DIVISION FOR STERILITY

VINCENT J. O'CONOR, M.D.
Chicago

Vasoligation, or surgical sterilization of the male, is done for various reasons: (a) with the idea of preventing the insane, the criminal or the perverse from producing offspring; (b) because the wife's health is said to be too precarious to risk bearing children, the wife being unable or refusing to undergo tubal ligation; (c) an agreement between husband and wife to prevent pregnancy; (d) to prevent the occurrence of epididymitis, a routine procedure in many clinics in the treatment of prostatism; (e) for the purpose of rejuvenation (Steinach), a false physiologic assumption and a clinical failure, and (f) mass sterilization for the purpose of racial limitation or extermination, as evidenced by recent Nazi treatment of persons of Jewish, Polish and other nationalities.

Because of the situation created in Europe by the mass sterilization procedures of bilateral vasoligation, or resection of the vas, this subject has recently been a matter of considerable discussion on the part of nonmedical persons.

Members of certain branches of the clergy have taken an active interest in this subject because of the marital implications resulting from this ordinarily uncommon premarital procedure. As far as I can determine, the general impression of all groups, lay, medical and religious, has been to the effect that not only is restitution of the normal lumen of the vas a difficult surgical procedure but also successful reanastomosis is so uncommonly attained as to make the procedure hardly worth undertaking. It is quite evident that many of these discussions have confused the procedure of anastomosis of epididymis and vas with reunion of the vas itself.

The person who seeks to have himself sterilized by vasoligation does so secretly and for what he considers strong personal reasons. The idea that ligation of the vas will be the solution of his problems is often conveyed to him by his family physician. The latter then refers him to a surgeon, usually a urologic one, for the operative procedure. The patient frequently encounters difficulty in persuading a competent surgeon to perform this procedure because in most states there is question as to its legality and the surgeon exposes himself to a possible suit for malpractice. Aside from the legal aspect there are often strong psychic, moral and religious reasons which the patient may have to overcome in order to justify the operation. It is natural, therefore, that in a private practice, in normal times, one would rarely encounter a person who sought restoration of fertility by another operation after having purposely submitted to vasectomy. For this reason no surgeon has individually had a large experience in attempting reunion of the vas after clean ligation.

A careful review of the literature reveals no observation of note on this subject. An occasional article describing a successful reunion of the vas was all that could be found. A serious review of this subject seems worth while at this time.

In 1919 I assisted Dr. William C. Quinby when he successfully reunited the left vas deferens in a patient who had purposely undergone bilateral vas resection in 1911. I have had the opportunity of verifying the success of this procedure by examining this man periodically for over twenty-five years.

Since 1920, I have performed reunion of the vas in 14 patients who had previously been sterilized by bilateral vas resection. Nine of these 14 men had a successful outcome as evidenced by a careful series of follow-up examinations over a period of two to fifteen years. The interval between resection and reunion of the vas was five to eighteen years, with an average of eight years. In every instance the epididymis, one or both sides, contained many motile spermatozoa. In all our patients bilateral reunion was done. The operation was not successful in 5 patients, 1 of whom was operated on twice in a period of three years. The cause of failure in these patients was not apparent to us.

An attempt to pool the knowledge of urologic surgeons on this subject was made by sending questionnaires to 1,240 recognized specialists. The following questions were asked:

1. How often have you attempted surgical reunion of the vas after its division for purposeful sterilization or when it had been ligated to prevent epididymitis?
2. In how many instances was the reunion successful as evidenced by the finding of spermatozoa in the semen?
3. Would you give a simple, brief description of the technic used?

Seven hundred and fifty urologists answered these questions; many of the replies were in detail and showed a considerable interest in this subject. The following tabulation will in brief summarize this information.

Questionnaires sent	1,240
Replies	750
Had never attempted the operation.....	615 surgeons
Operation performed one or more times by....	135 surgeons
Results Reported	
Number of operations performed.....	420
Operation a failure.....	239
Operation a success.....	160
Said to be a success but result really undetermined....	31

The 31 patients for whom the result is tabulated as undetermined were never examined after the operation but in each instance the wife was reported as having become pregnant.

No request was made for information on the incidence of proved spontaneous regeneration of the vasa after resection. However, 55 supposedly authentic instances were reported in the replies, and in each instance it was claimed that sections of the vasa were removed and examined microscopically at the time of operation. As one prominent urologist remarked, "I have noted several instances of proved spontaneous regeneration but have never attempted an operation to restore the lumen. If nature can do it so easily why can't we?"

TECHNIC

The operation for reunion of the vas should be made as simple as possible. I have followed the method used by Quinby, which consisted of freeing the embedded ends of the vas for a distance of 1 to 2 cm. and, after cutting away the occlusion scars at either end, performing an end to end anastomosis. In all our patients we performed incision or puncture of the epididymis (globus major) and verified the presence of active spermatozoa. In the first 6 patients on whom we

operated we tried to verify the patency of the lumen of the vas by passing a strand of silkworm gut to the region of the ejaculatory duct. The injection of methylene blue with recovery from the posterior urethra by catheter was done in 4 patients. Since operation was a failure in the fifth and sixth patients after this manipulation, we decided that the risk of trauma in this verification of patency of the lumen might defeat the purpose of the procedure. The last eight operations were done by end to end anastomosis, a strand of silkworm gut being used as a splint for a distance of 2.5 cm. above and below the juncture, the strand being brought out through the lower portion of the vas and through the scrotal incision. This splint was removed in six to ten days. In response to a request for a simple description of technic the following information was gained from the one hundred and thirty-five surgeons who had performed the operation:

End to end anastomosis.....	305
Side to side (lateral) anastomosis.....	29
Splint used (420 operations).....	299
Material:	
Silkworm gut or dermal.....	134
Horsehair.....	25
Tantalum wire }	
Stainless steel }	140
Silver wire }	

From the nature of the replies it was impossible numerically to correlate success or failure with the technic described. In five detailed reports the lateral anastomosis with a silkworm gut splint was successful.

Recent improvement in technic seems to depend on the satisfactory use of stainless steel or tantalum wire both as splinting material and for suture of the cut end of the vas. We have always used fine silver wire for this purpose. One of our urologists, Dr. Lewis Michelson, who has recently limited his work entirely to the treatment of male sterility, reported five successful procedures in 5 patients and was kind enough to detail the following technic:

Cut ends of the segments of vas were cleaned of scar tissue. Two stainless steel wires were introduced into the lumen on both proximal and distal segments for a distance of about 2 cm. The needle was pushed through the walls of both the distal and proximal segments of the vas, and they were then threaded on a cutting skin needle and passed through tunica and skin. Three anastomosing stainless steel wire sutures brought the cut ends of the vas together. Tunica, skin, etc. were closed with surgical gut. Both ends of the splinting wires were shotted. The wires were removed in seven to nine days. Anastomosing suture wires remained.

CONCLUSIONS

Reunion of the vas deferens after purposeful division to produce sterility, or to prevent epididymitis, may be successfully accomplished in from 35 to 40 per cent.

The possibility of success will naturally depend on the freedom of these tissues from previous inflammation.

Probably many of the reported failures were in patients with irreparable occlusion of the lumen of the vas at a point separate from the divided ends.

The normal testis continues to produce spermatozoa for an indefinite period after ligation of the vas. Renewal of the normal lumen permitted the normal escape of sperm eighteen years after surgical occlusion in 1 of our patients.

In view of this study the pessimistic outlook for relief of the vasectomized younger men in Europe should be revised and surgical aid offered to those persons who request it.

Special Article

CARCINOMA OF THE UTERUS, OVARY AND TUBE

NORMAN F. MILLER, M.D.
Ann Arbor, Michigan

This article is the sixth of a series to be published by the American Medical Association in cooperation with the American Cancer Society. The series is designed to aid in the early diagnosis of cancer and thereby to gain more effective results in treatment. When complete, the series will be published in book form by the W. B. Saunders Company under the sponsorship of the American Medical Association and the American Cancer Society.

The preparation of this article drew on an extensive experience covering twenty-seven years and the observation of well over 3,000 patients with cancer of the female generative organs. During the past fifteen years almost 2,500 patients have been processed through the Gynecology Tumor Conference under my direct supervision and with my participation. During the fifteen years of the Gynecology Tumor Conference work all patients seen have been carefully studied and evaluated, both before and after treatment. Furthermore, observation has continued throughout the years and my colleagues and I have maintained a 100 per cent follow-up on all patients seen. The fifteenth annual statistical report of this work is available for those interested in this type of cancer information. Except for a few tables which seem pertinent here the reader will not be burdened with statistical data.

While there is much that remains inscrutable regarding cancer the momentum of the fight against it is increasing. This is fortunate, for it is no second rate enemy. Evidence on this point is plentiful enough. Cancer now ranks second only to heart disease as a cause of death. There are now in the United States approximately 500,000 men, women and children with cancer, of which number about 170,000 will die this year. During the years of World War II the deaths due to cancer for the same period of time were approximately twice the number of American war casualties.

While much has already been accomplished toward the control of cancer it is essential that physicians realize how much more can be done with the tools now at their command. As the physician's experience with cancer increases he is apt to become pessimistic and too easily reconciled into accepting a high cancer mortality. This pessimism as well as the accompanying apathy are easily understood. Most cancers are in an advanced stage when first seen and their care does not give rise to optimism. The common habit of looking forward to a new cancer "cure" as the only solution to the problem serves as pap for this defeatist philosophy. It is easier to wait for a new cure, and this idea is nurtured by the present era of scientific "shenanigans." To assume that things are in a bad way and nothing much can be done about it until a new cure is available is faulty reasoning and the key to much of the present difficulty. All physicians confidently hope for a new cure, but if history repeats itself a new chemical or atomic cure will be of only limited value and its effectiveness will still be dependent

From the Department of Obstetrics and Gynecology, University of Michigan Hospital, Ann Arbor, Michigan.

on type of cancer and extent of involvement. A new therapeutic weapon will be most welcome, especially in the management of cancers not suitable for or responsive to either irradiation or surgery. But even though a new "cure" becomes available and proves to be as effective as surgery or irradiation—which would indeed be history making—physicians will, at most, find themselves at the beginning of another era such as occurred with the advent of surgery at the beginning of the present century and again fifteen to twenty years later with the arrival of clinically usable irradiation. In this day of far reaching discoveries and increasing scientific research the announcement of a new "cure" for cancer will not occasion great surprise but, unless its potentialities are considerably greater than either surgery or irradiation, the problem will remain as it is today, essentially one of prevention and early treatment. Unless this realistic point of view is adopted, anticipation of a new cure for cancer will minimize the value of existing weapons and encourage the adoption of a laissez faire attitude, both of which work against real progress in control of cancer. Actually there is plentiful reason to be hopeful. The increasing incidence of cancer is largely explainable on the basis of the fact that people live longer and therefore reach the cancer-susceptible age. Survival curves continue to show improvement. Most important, however, is the fact that physicians now have within their grasp the means to exert a powerful influence on many cancers, and especially cancer of the female genitalia.

Study and years of experience devoted to the problem of uterine cancer have convinced me that full realization and acceptance on the part of every practicing physician of the principles already mentioned and those to follow represents the most important single item in the control of uterine and many other cancers.

CANCER OF THE CERVIX

The uterine cervix is the commonest site for cancer of the female generative tract, constituting 65 per cent of all cancers of these organs.

The condition may exist quiescent in highly localized form for many years, but most cancers of the cervix are advanced when first seen. For this there are many reasons, chief among which are: (a) the undeveloped program of periodic health examinations and (b) delay

survival rate. Early cases permit attainment of a vastly greater five year survival rate (75 to 100 per cent).

Regular periodic examination of the cervix plus correction of minor lesions and biopsy for all suspicious lesions followed by prompt treatment in proved cases would reduce tremendously the mortality from this cause.

Showing approximate decrease per month (16 to 20 per cent) in chance for cure after onset of symptoms (spotting).

While the causation of cancer of the cervix is unknown much has been written concerning the possibility of a predisposing relationship between the common benign lesions of the cervix and cancer. Convincing evidence of such relationship is lacking, but even so the correction of all common cervical lesions is indicated on the grounds that cancer does not commonly appear in a healthy organ.

More than 90 per cent are of the epidermoid or squamous cell variety, most of the remainder being adenocarcinomas. In its earliest stages the cancer is most commonly found at the junction of the squamous epithelium of the vaginal face of the cervix and columnar epithelium of the cervical canal, from which point it spreads along or just beneath the surface until the entire vaginal cervix is involved. Further spread occurs by extension into the parametrial tissues, broad and sacrouterine ligaments, bladder and vaginal mucosa. Extension also takes place by way of the lymphatics to the regional lymph nodes, and it is the cancer cells in the parametrial tissues and involved lymph nodes that present the greatest obstacle to achieving a cure. Sterosis of the lower colon or rectum by the spreading neoplasm may become sufficiently marked to require colostomy. Pain due to osseous metastasis or encroachment on the spinal or sciatic nerves may require cordotomy for relief. Death may result from encroachment on and stenosis of the ureters. In some cases death is the result of terminal pneumonia caused by pulmonary metastasis and secondary pulmonary infection.

Symptoms of Cancer of the Cervix.—Early preinvasive lesions are commonly asymptomatic. When, however, invasion gets well under way, symptoms are usually present and become more pronounced with extension of the neoplasm. The principal and commonly the only symptom is spotting or bleeding. This may be slight at first and is characterized by being: (a) intermenstrual or irregular; (b) progressive, of increasing frequency and amount, and (c) prone to follow trauma, such as postcoital spotting.

Any woman presenting this symptom complex should be carefully examined, and a cervical or endometrial carcinoma should be suspected. About 15 per cent of patients with cancer of the cervix complain only of leukorrhea, a nonbloody watery, serous or purulent discharge. Some are symptom free, further emphasizing the need for periodic examination.

Diagnosis of Cancer of the Cervix.—While the advanced lesion presents little difficulty from a diagnostic point of view every case should be proved by

TABLE 1.—Waste of Time in Carcinoma of the Cervix

Reported by	Year	First Symptom to First Examination, Months	First Examination to Treatment, Months	Total Time Wasted, Months
Miller, N. F.: J. Iowa M. Soc. 23: 132-135, 1933	1929	6.2	6.0	12.2
Todd: J. Michigan M. Soc. 40: 191-196, 1941	1941	6.4	1.1	7.5
Miller, N. F., and Henderson, C. W.: Am. J. Obst. & Gynec. 52: 894-933, 1946	1946	5.0	4.5	9.5

on the part of patients in seeking medical advice after the onset of symptoms (table 1).

The significance of this waste of time is readily understandable by inspection of the chart based on spotting as the first symptom and positive evidence of parametrial thickening as the baseline for curability.

In spite of this delay the anatomic location and growth characteristics of the cancer are such that it is possible to achieve better than a 40 per cent five year absolute

taking tissue for histologic examination. In advanced cases this may require only removal of a piece of friable neoplastic tissue by means of a curet. In early and in questionable cases, tissue can be obtained for diagnostic purposes by means of any one of a number of readily obtainable biopsy forceps. Because these forceps do not remain sharp indefinitely and because the adjacent normal tissue encountered in early cases is tough, the imparting of a twisting motion to the biopsy forceps, once cervical tissue has been grasped between the jaws, will be found helpful. Since bleeding may follow biopsy it is well to have a small cautery, chemical coagulant or vaginal pack available for use. Serious bleeding at this time is seldom encountered. Biopsy taken by means of a scalpel is satisfactory but may lead to free bleeding and sometimes requires the placement of a stitch or two. In most instances biopsy of the cervix is an office procedure and requires no anesthesia.

When facilities are available for prompt evaluation the vaginal and cervical smear techniques now being enthusiastically received can be useful. Patients with positive smears should return for biopsy and histologic confirmation. One may look for considerable help in the future from the vaginal and cervical smear techniques as a means of screening for cervical and endometrial cancers. Taking the smear is simple enough; the interpretation, however, calls for skill in cytology. Perhaps, in time, pathologists generally will undertake such cytologic evaluation, making it possible for physicians to mail properly fixed slides to a qualified person for prompt evaluation.

Clinical Grouping and Histologic Grading of Cancer of the Cervix.—The clinical extent of the neoplastic growth is the most important single factor in determining prognosis. By classifying cancer of the cervix according to clinical extent one not only obtains a better idea of the patient's outlook but also facilitates intelligent discussion of the patient's condition. In evaluating placenta previa it makes considerable difference whether one is dealing with a marginal encroachment on, or complete covering of, the cervical os. So too, in working with cancer of the cervix, it is extremely helpful to know whether the lesion is early and confined to the cervix or advanced and associated with parametrial extension. A number of clinical classifications are used, their differences being of interest primarily to those who devote a good deal of their time to the problem of cancer of the cervix. For practical purposes there are four categories: 1. Clinical group I includes very early cases; early proved lesions, still confined to a small portion of the cervix. 2. Clinical group II includes more advanced cancers than in group I, but they are still confined to the cervix. Groups I and II are by all odds the most important. Cancers of the cervix in these stages present a favorable prognosis. With the adoption of a vigorous program of periodic check-up one may expect to see more patients in these stages and fewer in groups III and IV.

3. Clinical group III includes cancers of the cervix with questionable extension beyond the cervix, in which it is difficult to decide whether or not there is parametrial extension.

4. Clinical group IV includes all advanced cases, whether they reveal extension into vaginal vault, parametrial invasion or remote metastasis. While not hopeless they represent an advanced stage of the disease, one which is seen all too frequently today. This is a

large and inclusive group. It probably reflects: (a) unresponsiveness to educational programs, (b) the extreme need for universal periodic check-up examinations and (c) the quality of diagnostic facilities offered patients. As these things improve, as more and more women come regularly for check-up the number falling into group IV will decrease. Emphasis must be on the early lesion in the fight against cancer.

Evaluation of clinical extent requires care. It cannot be accomplished by vaginal examination alone but demands visualization of the cervix through a speculum and careful rectal palpation of the parametrial areas.

Histologic Grading: Histologic grading is largely the pathologist's responsibility. This may take the form of a frank statement to the effect that the neoplasm is of low grade malignancy or highly cancerous. The report may simply include a numerical rating such as I, II or III. In the latter case this numerical grading refers to degree of cell differentiation.

Thus, in histologic grade I the invading cells show considerable resemblance to the normal epithelium of the area involved. There is considerable differentiation. In grade III, the neoplastic cells are highly undifferentiated, having completely lost their resemblance to the normal cell type. Here is seen widespread infiltration of neoplastic cells with deep-staining nuclei of varying

TABLE 2.—*Surgical Rates for Carcinoma of the Cervix Based on Clinical Extent at Time of Treatment (University of Michigan)*

Clinical Group	5 Year		10 Year		15 Year	
	Number	Percentage Surviving	Number	Percentage Surviving	Number	Percentage Surviving
I	45	89	18	78	2	100
II	104	57	55	44	4	75
III	218	48	142	32	11	36
IV	669	36	317	12	14	0

sizes and numerous mitotic figures, reflecting a high degree of malignancy. Histologic grade II is an intermediate phase. There may still be seen in some areas a resemblance to the normal cell architecture, but this resemblance is only spotty or incomplete. The pathologist's report also indicates the type of malignant growth, such as the epidermoid or squamous cell and the glandular or adenocarcinoma.

In general, the clinical extent of the disease gives a more accurate index regarding ultimate prognosis and response to treatment than does the histologic grade of the neoplasm.

Prognosis for Cancer of the Cervix.—What can be said regarding chances for cure in cancer of the cervix? So much depends on the clinical stage of the disease when treatment is first instituted that it is best to discuss survival rates in relation to clinical grouping. When this is done evaluation of the patient's outlook becomes easier (table 2).

Table 2 represents data taken from the Fifteenth Annual Gynecological Tumor Conference Report¹ and indicates the average survival rate for a number of years for patients in the different clinical groups. The data shown in table 2 clearly demonstrate the importance of early diagnosis and treatment. Involvement of remote lymph nodes or early metastasis to other organs is uncommon; yet its occasional occurrence accounts for eventual death in some early cases in which treatment has been given.

1. Fifteenth Annual Gynecological Tumor Conference Report, 1931-1946, Univ. Hosp. Bull., Ann Arbor 13:82 (Aug.) 1947

Shall the Patient Be Told That She Has Cancer?—

There exists much difference of opinion regarding this point. Without entering on a lengthy discussion it may be stated that this practical question should not be answered dogmatically. In general, most women can be informed of the nature of their trouble in such a way as to make them fully aware, and yet the word cancer frequently can be avoided. It is my belief that patients who know the facts cooperate better. Furthermore, when the truth is known to both the patient and her family, the constant conniving and the many trying situations which arise for patient, family and physician can be avoided. While I definitely favor the patient's knowing what is wrong I do not believe it necessary or advisable to force the truth on those who have always avoided it and to whom mention of the word cancer is like sounding a death knell.

Treatment of Cancer of the Cervix.—Much has been written regarding the treatment of cancer; in fact, in the over-all picture, it may be said that the pen, by disseminating information, has been as mighty as the sword (scalpel). There are at present two acceptable methods of treatment for cancer of the cervix: (1) irradiation by means of high voltage roentgen rays and radium, and (2) radical surgical intervention.

I shall here attempt no more than brief mention of these methods, since I do not believe that the actual treatment of cancer of the cervix falls within the domain of the general physician. By surgical intervention I mean radical hysterectomy of the Wertheim type, bilateral salpingo-oophorectomy and pelvic lymphadenectomy. This is confined to selected cases and represents a revival of the one time mainstay in the management of cancer of the cervix. Sufficient evidence does not yet exist to indicate that such radical surgical treatment has more to offer the patient than does properly applied radiation. The point which I wish to make here is that if surgical treatment is to be used for cancer of the cervix it should be radical. The operation is not easy and unless properly performed may prove a missed opportunity for saving the patient's life. This, definitely, is not an operation for the untrained or inexperienced. What has been said for surgical treatment applies also to treatment by radiation. Few physicians have the facilities in the form of physical equipment or training for administering adequate high voltage roentgen ray or radium therapy. I do not consider the treatment of an occasional patient by inexperienced persons whose only knowledge of radioactivity is elementary either desirable or necessary. Undertreatment and occasionally overtreatment are the common result of such an arrangement. Undesirable sequelae are also more frequent. Good and permanent results require a proper understanding of both the disease and the weapons used to combat it. Opportunities exist for those especially interested in cancer work to receive the training and experience required for competence in this field. There are also tumor centers to which the patient may be referred for appropriate treatment. This becomes increasingly important as therapy grows more complicated and dangerous.

As previously stated, early diagnosis is the most important single factor in bringing about drastic reduction in both morbidity and mortality. Early diagnosis is to a large extent the domain of the general practitioner. It is here through periodic examination that he can achieve distinction for himself and accomplish the greatest good for his patients.

ENDOMETRIAL CARCINOMA

Cancer of the endometrium, less suitably called carcinoma of the "corpus" or "body," constitutes about 15 per cent of all cancers of the female generative tract. The disease occurs most frequently in postmenopausal women and is generally an adenocarcinoma. Clinical grouping is possible but not so satisfactory as for the cervix. This is generally based on size of the uterus, evidence of parametrial extension and uterine fixation. A small, freely movable uterus implies less extensive involvement and a more favorable prognosis than does the large uterus with fixation. The amount and histologic grade of the neoplasm are other important factors in determining prognosis.

Symptoms of Endometrial Carcinoma.—The commonest symptom in endometrial cancer is spotting or bleeding. This presents characteristics similar to those already listed for the cervix. About 25 per cent of patients with endometrial cancer have a semipurulent leukorrheal discharge as their principal complaint. Approximately 5 per cent have no symptoms, the disease being discovered incidentally or early, before sufficient involvement has taken place to produce symptoms. The appearance of spotting or irregular uterine bleeding is always suggestive. This is especially true in postmenopausal women revealing a healthy cervix.

Diagnosis of Endometrial Carcinoma.—Diagnosis is based on histologic confirmation of tissue obtained by curettage. The diagnosis may be suspected and even proved by careful cytologic examination of cervical smears. The decision as to whether such cells are or are not truly cancerous and whether they come from the cervical canal, endometrium, tube or ovary remains, for the present, a problem for the expert, subject to confirmation by biopsy (curettage) and routine histologic study. While curettage may at times be carried out as an office procedure in older parous women with a patulous cervix, hospitalization and thorough scraping of the uterine cavity with the patient under anesthesia is much more dependable. A positive report on tissue obtained by means of suction curettage is acceptable, but a negative report on tissue so obtained does not rule out the existence of an endometrial cancer. Slight bleeding following bimanual examination of the uterus is suggestive. When an endometrial cancer is present the trauma of bimanual examination is sometimes sufficient to disrupt the continuity of the neoplasm and result in slight bleeding. In the majority of cases the diagnosis is not difficult provided suggestive symptoms are watched for and the diagnostic procedures mentioned above are carried out.

Not all irregular spotting or bleeding in adult women is due to cancer, but in every instance cancer must be suspected until proved otherwise. Endocrinal imbalance is commonly noted at both ends of the menstrual span. In many menopausal women this is the cause of both the spotting complained of by the patient and the endometrial hyperplasia found associated with it. The widespread practice of administering estrogenic substances to both premenopausal and postmenopausal women for almost any and all symptoms has injected another cause for bleeding into the picture. The spotting or bleeding sometimes resulting from such medication can usually be distinguished from that of neoplastic origin in that the bleeding ceases and does not recur after use of the drug has been stopped.

While histologic examination of tissue obtained by diagnostic curettage is the proper method of arriving

at a positive diagnosis the procedure must not be abused. It is anticipated that physicians will exercise judgment in determining which patients shall be subjected to curettage. In the younger adult women spotting sometimes occurs at the time of ovulation. Here the history and absence of significant pelvic findings may be enough to warrant a probable diagnosis of ovulation bleeding and justify continued observation. A history of free use of the estrogens likewise indicates a period of observation after use of the drug has been stopped. If the bleeding is due to the estrogen it will soon cease and seldom recur. The presence of a small cervical polypus may give rise to spotting. Removal of the polypus should correct the situation unless cancer is also present. The bleeding associated with some uterine fibroids is commonly in the form of prolonged or increased menstruation. Endometrial cancer and uterine fibroids may coexist; hence in removing a uterus because of fibroids it is always well to open the specimen and grossly inspect the uterine cavity for evidence of a coexisting endometrial carcinoma. In the menopausal and premenopausal woman it is not so easy to be sure the bleeding is due to hormonal imbalance even though this appears to be the explanation. In all doubtful cases diagnostic curettage should be performed.

Treatment of Endometrial Carcinoma.—The advanced case of endometrial carcinoma permits no choice so far as treatment is concerned. If the patient is not excessively obese high voltage roentgen therapy in combination with a multiple capsule intrauterine application of radium is the principal standby. Patients have been cured by this method. The survival rate will naturally depend on the waste of time (table 3), the extent of neoplastic involvement and the quality of treatment.

High voltage and roentgen therapy or intracavitary radium therapy is also used in the management of early, more favorable cases, especially when the patient's general health or physical condition does not warrant a major operation. Most authorities in this field prefer to follow the radiation treatment by complete hysterectomy and bilateral salpingo-oophorectomy. The preoperative use of irradiation, either high voltage roentgen or multiple capsule intracavitary radium, followed in six to eight weeks by complete extirpation of the uterus and adnexa in properly selected cases, seems more logical and likely to contribute to greater permanence of cure. Histologic study of the previously irradiated removed uterus not infrequently reveals the presence of active neoplastic cell nests which, in time, could give rise to remote metastasis as well as local resurgence of the growth. Promptly recognized and properly treated endometrial or corpus carcinoma permits a good prognosis.

For reasons which have never been clear to me endometrial carcinoma has long been viewed by many physicians as a particularly benign type of cancer. This has not been borne out in fact. While a satisfactory survival curve may be demonstrated following full and adequate therapy this is not the case following incomplete treatment. Inadequate follow-up and the fact that the patient appeared to do well but died several years later are contributory factors in this connection. The practice of performing an incomplete hysterectomy for undiagnosed uterine bleeding is not a satisfactory way of preventing mortality from endometrial carcinoma. This practice leads to unnecessary operations and to inadequate treatment for the occasional case of endometrial cancer encountered. In my

opinion the patient is better treated when an effort is made to determine the cause of the bleeding and, if cancer is present, an acceptable program of irradiation is adopted, followed in six weeks by complete hysterectomy and removal of the appendages.

The purpose of the preoperative irradiation in these cases is to damage the neoplastic cells to the point where manipulative spread at the time of operation is unlikely. That this is accomplished by either roentgen rays or radium is proved by the necrosis and frequent obliteration of the endometrial lesion as revealed by careful histologic study following uterine extirpation. Destruction of neoplastic cells already in the parametrial tissues or in the pelvic lymph nodes is also a goal. The extent to which this is accomplished, however, is still an undetermined matter. Since cancer cells are sometimes found in the tubes and ovaries it is imperative that these organs be removed in all cases of proved endometrial carcinoma.

CARCINOMA OF THE OVARY

While the tumor-forming potentialities of ovarian tissue are considerable, ovarian carcinoma constitutes only 10 to 20 per cent of all cancers of the female reproductive organs. Though much less common than cancer of the cervix it presents a greater diagnostic and therapeutic problem. Like many internal cancers its onset

TABLE 3.—Waste of Time from Onset of First Symptom to Beginning of Treatment for Endometrial Carcinoma*

is silent, and early development generally occurs without accompanying symptoms. Because of this the neoplasm is commonly advanced before discovery.

There are many points about ovarian cancer of interest to the oncologist and pathologist which do not affect the general diagnosis and treatment of ovarian cancer, which I shall not inject into this discussion.

Ovarian cancer may occur in young women and children but is primarily a disease of older postmenopausal women, the average age being 52.

The degree of malignancy may range from the rapidly growing teratoma to the commoner, more slowly growing papillary cystadenocarcinoma. A variety of intermediate histologic types are seen. The cancer may be of primary origin or secondary, such as occurs with development in a preexisting serous or pseudomucinous cystadenoma. Metastatic cancer of the Krukenberg variety, which occurs secondarily to carcinoma of the gastrointestinal tract, represents another secondary variety. Consideration of the many histologic types of ovarian cancer is a comprehensive subject in itself and one which offers many problems. I shall not here become involved in this controversial aspect of the problem.

As stated earlier, while most incipient ovarian cancers are unaccompanied by symptoms, the functioning granulosa cell tumor by producing an excess of estrogenic hormone may cause uterine bleeding. The combination of ovarian tumor and uterine bleeding occurring in a preadolescent girl or a postmenopausal

especially suggestive of this type of neoplasm. Unfortunately, in the majority of patients with ovarian cancer abdominal enlargement, due to the tumor or an accompanying ascites commonly noted in advanced cases, is the first evidence suggesting the presence of an ovarian neoplasm. Loss of appetite, nausea, vomiting and cachexia due to encroachment on or involvement of the gastrointestinal tract are late manifestations. So, also, are pain and palpation of a flat abdominal mass, the so-called omental cake, caused by extensive neoplastic spread and omental involvement. The characteristic "silence" of early ovarian cancer is another reason why periodic physical examination is imperative in the control and prevention of pelvic cancer.

Diagnosis.—The diagnosis of ovarian cancer is made on the basis of histologic analysis of tumor tissue taken at the time of operation or, in advanced cases, on the basis of a biopsy of material from the posterior cul-de-sac or at the time of exploratory laparotomy. Diagnosis may also be confirmed by finding characteristic tumor cells in the ascitic fluid. In every case of ovarian enlargement, especially of the solid variety, the possibility of ovarian neoplasia must be kept in mind. During the menstrual years of the normal woman the ovaries may and frequently do undergo physiologic enlargement. Such tumescence seldom exceeds 5 cm. and commonly involutes or disappears within two to five months. Consequently cystic enlargements of this degree should be observed and their behavior noted. Progressive growth generally indicates a benign or malignant change and calls for surgical removal.

Management of Ovarian Cancer.—The management of ovarian neoplasia calls for clinical acumen. In general, complete surgical removal of both ovaries, tubes and the uterus is indicated in histologically diagnosed operable cases of ovarian cancer. However, since diagnosis is not possible until tissue has been obtained it is not always easy to carry out this pattern of treatment except where frozen section diagnosis is available during operation. The importance of cooperation between surgeon and pathologist in this connection is readily seen, especially in young women with a single ovarian neoplasm—freely movable but of questionable benignancy. Opportunity for frozen section diagnosis of tissue from the involved side and ruling out carcinoma will permit conservation of the normal ovary and uterus. Likewise, disclosure of a malignant neoplasm on the basis of histologic examination at the time of operation permits prompt and complete surgical extirpation, eliminating the necessity for a second laparotomy later. In the smaller hospitals where frozen section facilities and the services of a pathologist are not immediately available a conservative attitude toward the healthy-appearing ovary should be adopted. If the removed neoplasm proves to be cancer a second laparotomy for removal of the remaining ovary, uterus and tubes—though regrettable—is none the less indicated. There may be exceptions to this procedure when in a young woman the removed ovary reveals an extremely early lesion. Patients so treated in order to retain normal physiologic and child-bearing function must be closely observed, since ovarian malignant growths are not uncommonly a bilateral affair.

Preoperative or postoperative roentgen therapy may be desirable in all but the extremely early lesions in young women in whom a normal ovary was left. The value of such therapy has been demonstrated again and again. In some of the advanced cases of less

malignant growth the use of high voltage therapy (200 kilovolts or over) has occasionally resulted in sufficient improvement to make surgical extirpation possible. Indeed, in some instances the repeated use of high voltage roentgen therapy and surgery has permitted the prolongation of life for a decade or more.

We believe that every woman presenting the clinical picture of advanced ovarian carcinoma is entitled to exploration and biopsy, provided of course her physical condition permits. More than one person has been given a poor prognosis and short time to live on the strength of clinical evidence alone, and yet later exploration and histologic examination demonstrated a benign and operable neoplasm.

Prognosis.—While it is generally stated and borne out in fact that the prognosis for prolonged survival in ovarian cancer is not good, it must be remembered that histologic type of neoplasm and clinical stage of advancement at the time that treatment is instituted bear importantly on this situation. As pointed out earlier most patients do not report for diagnosis and treatment until the advanced state of the disease causes abdominal enlargement and discomfort. Obviously under such circumstances a good prognosis can scarcely be hoped for. The same may be said for the rare Krukenberg tumor, where ovarian involvement is secondary to a carcinomatous lesion of some portion of the gastrointestinal tract. Highly malignant teratomas, especially in young women, also offer a poor prognosis. The situation is not hopeless, however, provided that physicians recognize and strive to make their patients understand the extreme importance of, and vital need for, periodic pelvic examination. This is an absolute necessity for ovarian and other pelvic cancers, since prevention and early detection are the keys to the attainment of acceptable rates of survival.

CARCINOMA OF THE FALLOPIAN TUBE

Primary neoplastic involvement of the fallopian tube is exceedingly rare, constituting only 0.1 per cent of the cancers seen in the Gynecology Tumor Conference. Most primary tube cancers are of the papillary adenocarcinoma variety. During early growth the lesion is likely to be asymptomatic or silent in its development. Bimanual palpation of the pelvic viscera may, however, reveal a firm enlargement which cannot be accounted for on the basis of infection. The presence of an abnormal bloody vaginal discharge has been reported in some cases. Secondary carcinomatous involvement of the tube from a primary ovarian or uterine cancer may also occur.

Palpation of a firm or nodular movable tube may lead one to be suspicious, but it is unlikely that the diagnosis will be made without thorough investigation, as by cytologic study of a cervical smear, possibly visualization and biopsy through the cul-de-sac ("culdescopy") or at laparotomy. The treatment, if diagnosis is made in time, is preferably surgical extirpation of both tubes, ovaries and uterus. High voltage roentgen therapy might prove helpful as a postoperative procedure and as a life-prolonging measure in the inoperable case.

This discussion would be decidedly incomplete should I fail to emphasize what must now be clearly seen as the most important single factor in the control of pelvic cancer. While no one knows enough about cancer to permit dogmatic statements, long and careful study have clearly demonstrated one thing about which there can no longer be the slightest doubt, namely, the tremendous

value of prevention and early detection. It may be fantastic to hope that the day will come when every adult reports regularly for physical examination, but it is no idle dream to state that cancer of the pelvic organs (also cancer of the breast and skin) can be whipped through the general adoption of periodic physical examination. There is nothing new about this thought. It reflects the opinion and hope of most students of the cancer problem and it is time that real steps were taken to achieve this end. Why then has there been so much delay in the realization of regular periodic examination for all adult women? There are several reasons, only two of which will be considered here. The most important reasons lie with physicians. Many physicians are not familiar with the problem, and the comparatively few cases of cancer seen do not impress them with the prevalence of cancer or its importance as a cause of death. Neither do they recognize the vital part which they play in its control. Indeed, control of this disease lies predominantly in the realm of the general practitioner, not with the specialist. Many physicians are so busy that they cannot, and some for other reasons do not, encourage periodic examination. Many physicians hold that periodic examination imposes inconvenience and unnecessary expense on the patient and takes from the physician's limited time opportunity for the care of sick persons. There can be no denying that many physicians are pressed to the limit of their capacity, and doubtless many more physicians are needed to carry the medical load of this country. However, in attempting to keep people well and prevent cancer it is not asking too much to have the patient report every six months; yes, every six months for women over 40. Examination once a year is not enough, although it would make an acceptable beginning. The examination need not be expensive or excessively time consuming. Failure to advise periodic examination represents a dereliction of medical duty. Physicians also contribute toward delinquency of periodic examination by lacking the proper qualifications for making the examination. Healthy patients are frequently embarrassed and discouraged and commonly dissatisfied by the unresponsive attitude manifested by the physician. We no longer live in an age of blissful ignorance. The many channels today of propagandizing—both good and bad—have resulted in beginning public awareness concerning the advantages of preventive medicine. Therefore, it comes as a surprise to women trying to remain healthy to be told "Quit worrying. Go home and forget about it," or "Come back when you have symptoms." Surely women seeking to keep well are entitled to as much consideration on the part of the physician as are those who procrastinate to the point where early treatment is no longer possible. Physicians may not agree on some things concerning cancer but they do see eye to eye in the need to fight it. The taking of a careful history and periodic examination at regular intervals is the best means for carrying on the fight, and physicians, as the leaders in this fight, must not fail in their obligations or shirk their responsibilities. In this the general practitioner plays the key roll. By urging periodic examination for all patients and by making palpation of the pelvic viscera and visualization of the cervix, including biopsy when indicated, a routine part of every physical examination the death from cancer of many thousands of women can be prevented.

This is not the place to discuss the technic of pelvic examination except to say that its proper performance

can and should be learned by every physician. In emphasizing prevention I do not mean to imply that all women with abnormalities of the cervix or other pelvic organs require hospitalization and operation. Most common cervical lesions can be rectified without hospitalization by use of the cautery or other local treatment. Doubtful or suspicious lesions should be biopsied. Since only the physician can see the cervix, women must rely on him to correct conditions for which they would demand treatment were the cervix located on a visible portion of the body, such as the face.

The problem before physicians is not unsurmountable, but it is big and important enough to challenge the best fighting spirit of the medical profession.

Clinical Notes, Suggestions and New Instruments

CRANIAL ARTERITIS

Report of Its Occurrence in a Young Woman

LAWRENCE MEYERS, M.D.

and

JERE W. LORD Jr., M.D.
New York

The clinical syndrome of cranial arteritis has been described as "a rare, febrile, self-limited disease of variable duration and unknown etiology."¹ It has been observed to occur in both sexes, only in persons over the age of 50 years, and the local manifestations are usually associated with systemic symptoms and signs such as fever, malaise, lassitude, sweating and weakness. A mild leukocytosis is often seen.

Horton, Magath and Brown² first described the clinical entity of temporal arteritis in 1932, and recently Dantes³ stated that 36 patients with this disease had been reported in the literature.

Some observers⁴ have expressed the belief that the arteritis of the temporal artery may be part of a generalized process and that the clinical involvement of that artery is merely a local manifestation of an underlying widespread process.

In many of the patients ocular disturbances are present, and these range from retrobulbar pain to complete loss of vision.⁵ This difficulty has been ascribed to involvement of the retinal arteries by the same pathologic process seen in biopsies of the temporal artery.

The case herein reported is of clinical interest because of the age of occurrence of the disease and because the systemic manifestations were so mild. Another unusual feature in this patient is the fact that she experienced complete symptomatic relief immediately following removal of the involved segment of the left temporal artery and has remained well for the follow-up period of one year.

REPORT OF CASE

J. F., a white married housewife aged 22, was admitted to the New York Post-Graduate Hospital in December 1945 with the chief complaint of left-sided temporal headaches of three months' duration. Although the patient had experienced mild intermittent left-sided headaches for a period of one year, in

September 1945 the pain became sharply localized to the left temporal region and was associated with a deep-seated retrobulbar discomfort. The patient felt a throbbing sensation and tenderness in the temporal region. In addition there were mild general symptoms of chilliness, fever, malaise and weakness. Physical examination at that time revealed no abnormality

Fig. 1.—Photograph showing the swollen inflamed segment of the anterior branch of the left temporal artery. The involved area extended 3 cm. beyond the hair line.

except in the left temporal area, where the temporal artery above the eyebrow was thickened, beaded and tender and showed a feeble pulsation. The skin overlying it was reddened. The length of the entire involvement of the artery was 4 cm. (fig. 1). The general symptoms cleared in a few days, while the local manifestations persisted for three weeks. During the next two months the patient was troubled only by mild intermittent left-sided temporal headaches. Ophthalmologic examination by Dr. Rudolf Aebli at this time disclosed no abnormality. Three weeks before admission to the hospital the local symptoms and signs recurred with great intensity but without any of the constitutional symptoms. Examination on admission showed the left temporal artery to be thickened, beaded and tender and a faint pulsation was palpable. The skin overlying the artery was not reddened at this time. The other arteries of the scalp and extremities appeared normal on examination. The temperature, white blood cell count, sedimentation rate and urine were normal.

On December 22, with the patient under local anesthesia, the entire involved segment of the left temporal artery was removed. It was interesting to note that immediately after the operation the patient's headache and retrobulbar discomfort subsided.

Dr. A. E. Margulis, of the department of pathology, examined the specimen and made the following observations:

Gross Observations.—The specimen is a segment of artery 33 mm. long and 3 mm. in diameter. The lumen shows some variation in caliber and is generally small, but is free of thrombus. The wall of the vessel seems slightly thickened but is still pliable, and around the vessel there is a cuff of fibromuscular connective tissue.

Microscopic Observations.—This artery was cut serially from end to end and studied in hematoxylin-eosin, trichrome, van Gieson's elastica stain and Gram stain. The vessel shows both periarteritis and arteritis. The most striking change is the periarteritis. This appears as an eccentric cap in the perivascular tissues, surrounding one third to one half the perimeter of the vessel, and invades the surrounding fibrous and muscle tissue. The lesion extends for a considerable distance in the long axis of the artery and probably accounts for the nodularity before excision. This periarterial inflammation is an area of granulation tissue, numerous small calibered thin-walled and thick-walled vessels in an area of delicate fibrosis, infiltrated by lymphoid and plasma cells, the lymphoid cells sometimes forming follicles with germinal centers. There is also an occasional eosinophil. There are areas of hemorrhage and a few clumps of hemosiderin pigment. No giant cells are seen. The changes in the vessels involve all coats, and are proliferative and fibroblastic rather than exudative. The intima is much thickened in irregular fashion so that the luminal surface is scalloped; the lumen is much reduced in caliber but nowhere obliterated or filled with thrombus. The thickening of the intima is by a generally loose, finely fibrillar connective tissue in which there are found occasional groups of smooth muscle cells. The luminal surface is covered by an intact layer of slightly swollen endothelial cells. The internal elastica shows focal changes. There are areas of degeneration where it stains poorly and is finely crenated and areas where it is completely absent, at the margins of such areas shadows of elastic fibers being noted. The muscular coat shows principally focal atrophy, areas of partial disappearance of the muscle fibers and separation of the remaining muscle fibers by a finely fibrillar fibrosis. No

Fig. 2.—Photomicrograph enlarged approximately thirty-eight times, showing cross section of resected temporal artery. The most pronounced inflammatory changes are in the perivascular region. A detailed description is given in the text.

giant cells are noted in any coats of the vessels. Bacteria are not demonstrated either in the wall of the vessel or in the perivascular inflammation.

Diagnosis.—There is periarteritis and arteritis of a segment of the temporal artery.

Note.—The changes described do not conform to the histologic changes reputed to occur in the syndrome of temporal arteritis. More specifically there is not the exudative giant cell arteritis which has been found in the active phases of this recently described syndrome. It must be emphasized however that not all the biopsies or autopsies performed in this disease have shown such a giant cell arteritis. Only relatively few histologic studies of the clinical syndrome of temporal arteritis have been made, and it is doubtful that the complete life cycle of this lesion has been delineated. Clinically it is known that the lesion regresses and that the artery apparently returns to normal, but not much is known about the histologic structure of the healing or late stages (fig. 2).

Follow-Up.—The patient has been seen at frequent intervals during the past twelve months and has remained entirely free from headaches and retrobulbar pain. The operative site has remained well healed and the proximal normal left temporal artery is compressible and nontender and pulsates normally.

Comment.—This patient had typical physical manifestations of cranial arteritis. Microscopically, however, the picture is at variance with the classical pathologic findings in that no giant cells were seen and there was no evidence of a thrombus. It is worthy of note that our patient showed less evidence of inflammation locally in the region of the temporal artery at the time of operation than at the onset three months before. Therefore it is conceivable that the microscopic specimen examined represents a late stage in the life cycle of this disease not reported previously.

This is the first patient to our knowledge who has manifested the symptoms of the syndrome, cranial arteritis, at such an early age.

SUMMARY

A case of cranial arteritis occurring in a 22 year old white woman is reported and represents the first instance in which this condition has been observed under the age of 50 years. After removal of the diseased segment of the temporal artery the patient has remained free of symptoms for one year.

DICUMAROL POISONING

ARTHUR J. DRAPER Jr., M.D.
Charlotte, N. C.

Those experienced in the clinical use of "dicumarol" have repeatedly emphasized its dangerous possibilities,¹ and yet instances of intoxication due to inadequately controlled dosage continue to be reported.² The case to be presented is one of self medication with dicumarol which resulted in widespread hemorrhages of serious import.

REPORT OF A CASE

Miss V. H., a 46 year old graduate nurse, entered Charlotte Memorial Hospital July 4, 1947, complaining of pain across the middle of the back, tightness in the upper part of the abdomen and the passage of bloody urine for two days. On the first day of illness she awoke with severe aching across the lower dorsal region bilaterally, somewhat relieved by three acetylsalicylic acid tablets, a heating pad and bed rest. That night she passed notably dark urine. Next day, dosage with magnesia magma followed by two enemas produced several soft, grossly bloody stools; grossly bloody urine was voided on two more

occasions. Backache continued, and the patient noted for the first time large bruises over the trunk, buttocks, forearms, thighs and face. A soft clot in the right upper gum had oozed most of the day.

Close questioning with regard to drug habits elicited at first only the usual reply of acetylsalicylic acid and various pro-

Note the steady response of the prothrombin level to intravenous administration of vitamin K and the accompanying prompt drop in coagulation time.

prietary headache remedies; at length, however, the patient volunteered that she had taken "eight or ten tablets" of dicumarol for "arthritis," a procedure said to have been suggested by a newspaper article. Originally she said that she had taken them "last week," but this statement was amended to "three weeks ago." The exact dosage and duration of self medication with dicumarol remain in doubt.

Past history and systemic review disclosed no evidence of hepatic or renal disease, and there had never before been any bleeding tendency. "Migraine headache" had occurred for many years, but not for the past seven. Fleeting pains throughout the limbs and trunk when the patient arose in the mornings led to the diagnosis of arthritis. No joint swelling, redness, heat or limitation of motion had ever been observed.

Physical examination revealed a slightly obese, somewhat pale white woman of middle age who showed no signs of shock. The blood pressure was 118 systolic and 70 diastolic; the pulse rate was 90. Over the skin of the forearms and thighs were scattered deep purple ecchymoses some 2 cm. in diameter. Similar lesions were apparent in both flanks where the girdle was tightest. In the left buttock was a large ecchymotic area some 10 cm. wide, the site of a liver injection given two days before. Scattered petechiae were easily seen over the chest, forearms and calves and in the mucous membrane of the mouth. The conjunctivae and fundi were clear. Except for slight tenderness on deep palpation of the right upper quadrant there were no other significant findings.

Emergency laboratory studies showed a hemoglobin level of 10.5 Gm. (72 per cent) and a leukocyte count of 7,200. A tourniquet applied between systolic and diastolic blood pressure for five minutes to the upper part of the arm produced 20 to 25 petechiae in the antecubital space. More complete studies next day gave the following results: red blood cells, 3,740,000; white blood cells, 15,800; hemoglobin, 10.0 Gm. (70 per cent); platelet count, 289,440; bleeding time five minutes and thirty seconds; coagulation time (capillary tube method) ten minutes plus (the procedure was discontinued after ten minutes), and the prothrombin level was 1. per cent. A fragility test showed

W.: in discussion on Allen, A. W.; Linton, R. R., and Donaldson, G. A.: Venous Thrombosis and Pulmonary Embolism, *J. A. M. A.* 133: 1276 (April 26) 1947.

beginning hemolysis at 0.40 cc. of 1 per cent sodium chloride, ending at 0.20, against a control of 0.44 and 0.28 respectively. The urine was dark red and loaded with red blood cells on microscopic examination.

On July 5, the day following admission, the patient received 30 mg. of "synkayvite" (a preparation of vitamin K) intramuscularly in divided doses, 60 mg. of "synkayvite" intravenously twice six hours apart, and a transfusion of 500 cc. of fresh citrated whole blood. Next day 60 mg. of "synkayvite" was given intravenously, a dosage repeated on the fifth and sixth hospital days. By the third day the patient showed much subjective improvement. Her backache and abdominal discomfort had disappeared, and she was eating and sleeping well. The urine remained bloody for two days, dark for two more days, but was entirely clear thereafter. A stool specimen secured by enema on the fifth hospital day gave a 2 plus benzidine reaction. The temperature beginning the day following admission rose daily to 100.4 to 101.4 F., but returned to normal levels by the eighth day. The prothrombin level rose successively to 55 per cent on the fourth day, 50 per cent on the sixth day and 98 per cent on the eighth day. The coagulation time fell by the fifth day to two minutes six seconds, and the bleeding time to one minute fifteen seconds. Blood counts had been restored to normal; on the seventh day the red cell count was 4,500,000, with a hemoglobin level of 12.6 Gm. and a white cell count of 7,250. Since the patient had become asymptomatic and observed deviations of the clotting mechanism had been restored to normal, she was discharged on the eighth hospital day.

COMMENT

In view of the pronounced depression of the prothrombin level with associated elevation of coagulation time, both of which responded in striking fashion to the administration of vitamin K and fresh whole blood transfusion, there can be little doubt of the diagnosis of dicumarol intoxication. The history of dicumarol medication is definite, even though the exact quantity taken and period of administration remain obscure. The fever, I feel, can be accounted for by extensive bleeding into the tissues such as occurs in thrombopenic purpura; similar observations have been recorded by Shlevin^{2a} and Wright.³ The slight prolongation of bleeding time is interesting in view of reports by other authors showing no deviation of this test from normal.⁴

Dicumarol toxicity, established by the brilliant investigations of Link and his co-workers into the cause of hemorrhagic disease of cattle,⁵ led to its use as an anticoagulant in certain thrombotic disorders of man.⁶ When controlled by frequent accurate estimations of the prothrombin level, however, toxic reactions can be kept at a minimum. E. V. Allen reported "major bleeding" in only 1.9 per cent of 1,686 postoperative cases.^{1c} Such bleeding, according to Barker,^{1b} is almost always from surgical wounds, especially in gynecologic procedures. Definite bleeding, as Barker stated elsewhere,^{1c} is rare if the prothrombin level does not fall below 10 per cent of normal and even then occurs in only 4 per cent of such cases; multiple widespread ecchymoses and hemorrhages, he continued, are extremely rare. No frank hemorrhages occurred in the 50 cases reported by Peters,^{6b} nor were hemorrhagic phenomena observed in the 162 patients given dicumarol by A. W. Allen.⁷ Because identical amounts of the drug may produce widely different effects on the prothrombin level in different persons, or at different times in the same, accurate daily checks on the prothrombin level must be made.^{1c} Cromer found that 27 per cent of 93 patients showed a rise in prothrombin time to over sixty

seconds after one or two doses, a rise sustained, in many cases, for several days.⁸ Four of 60 patients treated by Levan showed gross hematuria on ordinary dosage.^{1d} Fatalities directly attributable to hemorrhage induced by dicumarol have not occurred in well followed cases. The two deaths described by E. V. Allen,^{1c} 2 by A. W. Allen,⁷ and 1 by Butsch and Stewart⁹ all were observed after major operation or in the presence of malignant growths, where the fatal hemorrhage could have occurred in the absence of dicumarol. Therefore, while major bleeding might rarely take place in closely followed cases under dicumarol therapy, untoward reactions are almost always avoidable.

Such is not the case when dicumarol has been administered without a constant check of the prothrombin level. Shlevin and Lederer^{2a} have reported a fatality in a patient who had, before coming under the care, received 2,100 mg. of dicumarol without one such check. Engorgement of all blood vessels except the larger trunks was seen at necropsy, and hemorrhages had occurred in the renal pelves, bladder and brain. Massive hematuria following operation has been observed in several cases by Hendrick.^{2b}

The therapy of frank hemorrhage due to dicumarol intoxication is now simple and satisfactory. As Crom and Barker have shown,⁸ the prothrombin level responds rapidly to massive intravenous doses of vitamin K; 64 mg. of menadione brought the level to safe limits in 35 of 37 patients within eighteen hours. Allen^{1c} now recommends 30 to 60 mg. of vitamin K intravenously; Levan, 60 mg.,^{1d} the frequency of administration depending on the prothrombin level. Fresh blood transfusion, though it does not give a sustained decrease in prothrombin time, forms a valuable adjuvant,^{1b} especially when appreciable loss of blood has occurred.

CONCLUSIONS

A case showing hemorrhagic diathesis due to accidental poisoning with self-administered "dicumarol" is reported. The prevention and treatment of dicumarol intoxication are briefly discussed. The laity, as well as physicians, should be warned against indiscriminate use of a potentially dangerous drug, and popularizers of medical discovery should exert the utmost discretion in their articles concerning dicumarol.

NOCARDIOSIS

Nocardia Asteroides Infection Simulating Pulmonary Tuberculosis

Cannon Falls, Minn.

A review of the literature reveals that infection due to *Nocardia asteroides* (formerly called "Actinomyces asteroides") is not common. In the large majority of cases reported, the diagnosis has been made at the time of necropsy. In those instances in which the diagnosis was established during life, the organism usually was demonstrated late in the course of the disease. Only an occasional recovery has been reported. Before the introduction of sulfonamide drugs and antibiotics no satisfactory treatment was available. In 1921, Henrici and Gardner² reviewed the literature on the acid-fast actinomycetes.

2. Henrici, A. T., and Gardner, E. L.: The Acidfast Actinomycetes, with a Report of a Case from Which a New Species was Isolated, J. Infect. Dis. **28**: 232-248, 1921.

They were able to find 26 such cases and they added 1 case, in which the patient was suffering with what appeared to be a pulmonary infection. The organism isolated from the sputum was an acid-fast actinomycete which they described under the name of *Actinomyces gypsoidei*. Later Henrici³ expressed the opinion that this organism had no characteristics by which it could be differentiated from *Actinomyces asteroides*. Of the group of 26 cases which Henrici and Gardner collected from the literature, the only case in which recovery was reported was an example of Madura foot. Recovery followed amputation of the infected foot. In the case reported by Henrici and Gardner, the patient was treated with antigen made from the cultures but the final outcome in this case is uncertain.

Goldsworthy⁴ added another case to the literature in 1937; this infection also was fatal. Another case of fatal outcome was reported by Kessel and Goolden⁵ in 1938. At about this time the use of sulfonamide therapy was becoming widespread. Benbow, Smith and Grimson,⁶ in 1944, again reviewed the literature and reported 2 cases in which surgical drainage, vitamin therapy, roentgen therapy and sulfonamide therapy were used; both patients recovered. In 1945, Binford and Lane⁷ reported another case in which the infection was fatal and the diagnosis was made at the time of necropsy. The literature on the general subject was again reviewed in 1946 by Kirby and McNaught.⁸ They added 2 cases, in both of which the outcome was fatal. One of the patients reported by them received short courses of sulfadiazine therapy, each time with improvement, but the patient was seen late in the course of his illness and sulfonamide therapy was not adequate. Including the cases reported by Kirby and McNaught, up to the time of their report the total number of cases was 34. Of the 34, only 3 could be considered for certain as examples of recovery. One was the case of Madura foot mentioned previously and the other 2 were those in which the patients received the benefit of sulfonamide therapy in addition to surgical drainage.

In addition to the cases mentioned and reported by Kirby and McNaught, there are two other reports in the literature, both of which appeared in 1946. One was a case reported by Shaw, Holt and Ray.⁹ The patient was a 32 year old white woman suffering with a pulmonary infection simulating tuberculosis. The diagnosis was established by bacteriologic study of the pleural fluid. The recovery of the patient was attributed to the use of penicillin combined with surgical drainage of the empyema cavity as well as surgical drainage of an associated abscess in the right buttock. It should be mentioned, however, that this patient received in addition potassium iodide, thymol and sulfadiazine. The use of sulfadiazine was followed by definite clinical improvement. The other report referred to earlier in this paragraph is that by Calero.¹⁰ The patient was a 12 year old white girl suffering with "pleuropulmonary fistulae." *N. asteroides* was isolated from the fluid obtained from the fistulas and from the sputum. This patient received several courses of sulfonamide drugs and two courses of penicillin. She was dismissed as cured; however, at the time of dismissal the sedimentation rate was still elevated. Calero pointed out that the final outcome could not be stated at the time of the report.

It is evident that if one excludes the case of Madura foot cured by amputation and the case in which the disease was treated with an antigen and in which the final outcome is not known, only 4 of the 36 cases could be considered as clearcut examples of recovery. All 4 patients received sulfonamide therapy in addition to other forms of treatment. Two received penicillin. In view of studies carried out in our laboratory,¹¹ as well as by Drake,¹² there is reason to doubt whether *N. asteroides* is sensitive to the action of penicillin.

We are reporting a case of *Nocardia asteroides* infection simulating pulmonary tuberculosis in which all studies failed to confirm the diagnosis of tuberculosis. On the other hand, cultures of empyema fluid were positive for *N. asteroides*. Penicillin and streptomycin therapy had no effect on the course of this infection. Intensive sulfadiazine therapy was followed by what appears to be a complete recovery. The case to be reported is of further interest because no surgical or other treatment was employed after intensive sulfadiazine therapy was begun both by the intrapleural and by the oral route. Cultures did not become negative until after this treatment was instituted and, as has already been stated, penicillin and streptomycin were ineffective.

REPORT OF CASE

The patient was a white male physician, 26 years of age. He registered first at the Mayo Clinic on April 27, 1944. According to the history, he was said to have arrested minimal pulmonary tuberculosis. The Mantoux reaction had been negative in 1940 but had become positive in May 1942. Roentgen-

Fig. 1.—A, Sept. 4, 1944. Infiltration laterally in the first and second anterior interspaces on the right immediately prior to the institution of pneumothorax therapy. B, Oct. 18, 1944. Pneumothorax on the right after closed pneumonolysis.

ograms of the thorax taken at the time, however, were reported as negative. In November 1943, at which time the patient applied for a commission in the armed services, a routine roentgenogram of the thorax was said to have revealed a minimal lesion in the apex of the right lung. Repeated examinations of sputum did not reveal acid-fast bacilli. On one occasion a questionable positive sputum was reported, but this was never confirmed. Cultures of the sputum were also negative. In spite of these negative results but because of the roentgenographic findings, the patient spent four months on a modified rest regimen.

The patient was then examined at the clinic, and roentgenograms of the thorax revealed that during this interval the minimal lesion in the apex of the right lung had become smaller. Two months later (June 28, 1944) a follow-up roentgenogram revealed an increase of the infiltration in the apex of the right lung with slight fibrosis surrounding an area of questionable cavitation (fig. 1A).

The patient then was referred to Mineral Springs Sanatorium, Cannon Falls, Minn. After a short period of rest in bed, artificial pneumothorax on the right side was instituted. This treatment was given on the request of the patient despite the fact that efforts to obtain bacteriologic proof of the presence of tuberculosis had failed. Guinea pig inoculations of gastric contents obtained shortly before his admission to the sanatorium

were negative for *Mycobacterium tuberculosis*. The patient obtained an excellent collapse which was improved by closed pneumonolysis of a small adhesive band (fig. 1B).

Three months after admission to the sanatorium the patient performed part time work. He continued in good health for the next ten months. During this interval he received weekly pneumothorax refills. In October 1945 he contracted an acute respiratory infection with cough. Roentgenologic examination of the thorax at that time revealed an area of infiltration in the lower lobe of the right lung beneath the pneumothorax. At that time examination of the blood revealed the concentration of hemoglobin to be 16 Gm. per one hundred cubic centimeters of blood. Leukocytes numbered 8,200 per cubic millimeter of blood and the sedimentation rate by the Westergren method was 8 mm. in one hour.

The patient was hospitalized and was given 80,000 units of penicillin intramuscularly each day for one week. Under this management the area of infiltration in the lower lobe of the right lung cleared. He was dismissed from the hospital with a slight residual nonproductive cough. One month later he was readmitted to the hospital because of fever with sweating, generalized malaise and cough. At the time of his admission his temperature was 99 F. and the pulse rate was 100 beats per minute. The laboratory studies gave negative results at the time of this admission except for the fact that the sedimentation rate had now risen to 80 mm. in one hour by the Westergren method. Three examinations of sputum at that time were negative for acid-fast bacilli. No tubercle bacilli could be identified

Fig. 2.—A, Jan. 28, 1946. Empyema in the right pleural space with fluid level in the sixth interspace posteriorly. B, Jan. 9, 1947. Present status of patient. Pleural pocket on the right obliterated with residual thickened pleura and some contraction of the right hemithoracic cage, specially at the apex.

in gastric washings either by smear or by culture. Penicillin therapy was again begun. The patient received 160,000 units daily by the intramuscular route for one month. Roentgenograms of the thorax at weekly intervals revealed gradually increasing amounts of fluid in the right pleural space (fig. 2A). At the end of this course of penicillin therapy a bronchoscopic examination was performed but the results were negative. The sedimentation rate at this time was 101 mm. in one hour by the Westergren method. Two weeks later thoracentesis on the right side was performed and 200 cc. of clear fluid was removed. Cultures of this fluid were reported negative. Smears for tuberculosis were negative and in 2 guinea pigs inoculated with this material evidence of tuberculosis failed to develop.

The patient then was referred back to Mineral Springs Sanatorium for further care. Aspirations of the thorax were carried out three times per week for the next six or seven weeks. The amount of fluid withdrawn varied from 3 to 6 fluidounces (89 to 177 cc.). The fluid was clear and attempts to demonstrate the presence of acid-fast bacilli were unsuccessful. On March 4, 1946, for the first time purulent material was obtained at the time of aspiration. Since tuberculosis was suspected at all times, 0.25 to 0.5 Gm. of streptomycin was left in the pleural space after each aspiration. This procedure was continued every two to five days for the next four weeks. Subsequently an attempt was made to obliterate the space by an oleothorax. This procedure was soon abandoned as not being feasible.

Bacteriologic studies of the first purulent material revealed the presence of numerous colonies of *N. asteroides* in pure

culture. The presence of this organism in the pleural fluid was demonstrated repeatedly. The pleural fluid soon became thick and hemorrhagic. On several occasions penicillin (60,000 to 100,000 units) was added to the 0.5 Gm. of streptomycin introduced into the pleural cavity. In spite of this treatment, bacteriologic studies of the pleural fluid continued to show many colonies of *N. asteroides*.

The organism was tested for sensitivity to streptomycin and penicillin. Growth on blood agar was inhibited by 5 units of streptomycin per cubic centimeter of medium but not by 2.5 units. Growth was not inhibited by 100 units of penicillin per cubic centimeter of medium.

Tests for sensitivity to sulfadiazine were carried out on plates of a synthetic medium used by MacLeod,¹³ to which agar had been added. The organism was completely inhibited by sulfadiazine in dilutions of 1:80,000 (1.25 mg. per hundred cubic centimeters) and almost completely inhibited by dilutions of 1:160,000.

A substance for cutaneous tests was obtained from another strain of *N. asteroides* isolated some years ago. The material was prepared according to the method described by Drake and Henrici¹⁴ for the crude extract of unheated defatted organisms. After filtration through a Berkefeld candle and culture for sterility, 0.5 cc. was injected intracutaneously on the volar surface of the forearm of the patient and of a control person having skin of a similar texture. Twenty-four hours later at the site of injection on the patient there was a well demarcated, raised, dark strawberry red area of edema 13 mm. in diameter. The reaction was accentuated at forty-eight hours. Seven days after injection there remained a clearly outlined but faint, pigmented area at the site of the reaction. Twenty-four hours after injection the control showed a faint erythema but no edema at the site of injection. The erythema had faded in forty-eight hours and left no residual pigmentation.

The edematous reaction to the extract, occurring in the patient and becoming maximal at forty-eight hours, was similar to that produced by Drake and Henrici using a similar extract in animals experimentally sensitized to *N. asteroides*. It was evident, however, that the cutaneous sensitivity of the patient to the *N. asteroides* extract was not of the order of activity to tuberculin usually seen in patients suffering with tuberculosis.

Administration of streptomycin and penicillin was discontinued on April 8, 1946. Two and a half grams of sulfadiazine in 20 cc. of isotonic solution of sodium chloride was administered by the intrapleural route. Sulfadiazine was administered orally in amounts of 90 grains (6 Gm.) per day. Specimens of the pleural fluid obtained on the second, fourth and seventh days after the initiation of sulfonamide therapy and cultured on mediums containing para-aminobenzoic acid yielded a few colonies of *N. asteroides*. Previous cultures had yielded many colonies. Specimens obtained nine days after the initiation of sulfonamide therapy required concentration to produce any growth.

Then it was decided to treat the patient even more intensively with sulfadiazine. The oral daily dose was increased to 135 grains (9 Gm.) per day and the patient also was given approximately the same amount of sodium bicarbonate orally. Complete examinations of the blood and urine were performed every second day following the institution of this program, which was continued for five months. On several occasions sulfadiazine therapy was interrupted for twenty-four hours because of the appearance of hematuria. Except for these intervals, the patient received continuous treatment with sulfadiazine. At the beginning the instillations were performed twice or three times per week. Later the injections were made at weekly intervals. In the beginning the amount administered was 5 Gm. in 40 cc. of isotonic solution of sodium chloride. Later

13. MacLeod, C. M.: The Inhibition of the Bacteriostatic Action of Sulfonamide Drugs by Substances of Animal and Bacterial Origin. *J. Exper. Med.* 72: 217-232 (Sept.) 1940.

14. Drake, C. H., and Henrici, A. T.: *Nocardia Asteroides*: Its Pathogenicity and Allergic Properties. *Am. Rev. Tuberc.* 48: 184-198 (Sept.) 1943.

the volume of the mixture was decreased. The sulfadiazine levels were held between 7 and 16 mg. per hundred cubic centimeters of blood. The sulfadiazine level in the pleural fluid varied between 24 and 86 mg. per hundred cubic centimeters. Specimens of pleural fluid obtained on the fourteenth, sixteenth and seventeenth days after the initiation of sulfadiazine therapy did not show growth of organisms on unconcentrated cultures. When the material was concentrated by centrifugation and plated on medium containing para-aminobenzoic acid an occasional colony of *N. asteroides* was found. *N. asteroides* isolated one month after the institution of sulfadiazine therapy was found to be as sensitive to the drug as the cultures isolated before such treatment was started. The last positive culture was obtained on May 16, thirty-eight days after sulfadiazine therapy was started. Five subsequent cultures were negative.

Three weeks after the beginning of sulfadiazine therapy, only 1 fluidounce (30 cc.) of cloudy fluid could be obtained at each aspiration. Intrapleural pressures varied from minus 7 to plus 11 cm. of water. Approximately ten weeks after the onset of this form of treatment the character of the pleural fluid changed abruptly from turbid to bloody and then to a clear amber type of fluid. A few days later only 8 cc. of pleural fluid could be aspirated. Intrapleural sulfadiazine therapy was discontinued. One week later no fluid or pleural pocket could be demonstrated. During treatment with sulfadiazine the patient showed marked clinical improvement. His cough subsided. He gained weight and also regained his appetite and sense of well-being. Roentgenographic examination of the thorax revealed improvement which paralleled his clinical course.

Oral sulfadiazine therapy was continued for a total of approximately five months. The total amount of sulfadiazine administered by the intrapleural route was 75 Gm. The total amount administered by the oral route was 1,268 Gm. (approximately 3.4 pounds [apothecaries' weight]).

At the time of this writing, there is little evidence of pulmonary disease (fig. 2B). The physical examination gives negative results, as do the complete blood studies and urinalysis. The sedimentation rate is 8 mm. in one hour by the Westergren method. The patient has not received treatment for fourteen months. He has been working steadily at his former occupation and is in excellent general health.

SUMMARY AND CONCLUSIONS

Nocardiosis is not a new disease but it may likely be an unrecognized one. The infection is due to *Nocardia asteroides*, formerly called "Actinomyces asteroides." The clinician will do well to consider the presence of this disease in lesions simulating tuberculosis when bacteriologic confirmation of the diagnosis of tuberculosis is lacking. Before the era of modern chemotherapy, recovery from this infection was exceedingly rare. Of the 36 cases reported in the literature through 1946, only 4 (excluding a case of Madura foot cured by amputation) could be considered clearcut examples of recovery. In all 4 cases the patients received sulfonamide therapy in one form or another in addition to other forms of treatment. We have reported a case of nocardiosis simulating pulmonary tuberculosis in which complete recovery appeared to have followed intensive therapy with sulfadiazine without surgical intervention. The antibiotics, penicillin and streptomycin, had failed to control the infection.

It would appear from the studies carried out in our laboratory as well as those carried out elsewhere that sulfadiazine is the drug of choice in the treatment of nocardiosis. The sensitivity of *N. asteroides* to penicillin and streptomycin is not sufficiently great to suggest that these agents will control the infection unless, perhaps, they are combined with sulfonamide therapy.

It is suggested that the term "actinomycosis" be restricted to infection due to *Actinomyces bovis* and that "nocardiosis" be applied to infection due to *Nocardia asteroides*. It seems reasonable to conclude that patients suffering with this infection should recover if the condition is diagnosed early and is treated intensively with sulfadiazine.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports.

HOWARD A. CARTER, Secretary.

CHRISTENSEN HEAT CRADLE ACCEPTABLE

Manufacturer: Christensen Heat Cradle Company, 535 Bright Street, San Francisco.

The Christensen Heat Cradle is a baker which consists of an adjustable and collapsible steel framework 61 cm. (24 inches)

Christensen
Heat Cradle

high, 61 cm. (24 inches) wide and 46 cm. (18 inches) long and weighs approximately 3.6 Kg. (8 pounds). It supports three pairs of electric light-bulbs of elongated form in such a way that when covered by bedclothes it forms a tent under which heat can be applied to an upper extremity or to one or both lower extremities of a patient. The height of the lights can be adjusted, and each has its own switch. Each light is guarded by an arrangement of metal loops which not only protect the light from strains and blows but also protect the skin from contact, which, as is well

known, need not be longer than momentary to cause unfortunate burns in some patients.

The Council on Physical Medicine voted to include the Christensen Heat Cradle in its list of accepted devices.

SANBORN METABULATOR 1947 ACCEPTABLE

Manufacturer: Sanborn Company, 39 Osborn Street, Cambridge 39, Mass.

The Sanborn Metabulator 1947 (Sanborn Metabolism Tester) is an instrument designed for the determination of basal metabolic rates. It is a wooden cabinet with four legs mounted on casters, which make it easily portable. Its over-all dimensions are 33 by 65 by 89 cm. (13 by 25½ by 35 inches), and its weight uncrated is 43 Kg. (95 pounds). A motor-driven fan circulates the air in the system, which consists of a bellows, a container for the absorbent for carbon dioxide and a set of rubber tubes leading to the mouthpiece and the patient. The bellows bears a recording device, which traces on a motor-driven drum. The tracing is made by a stylus on a special type of paper that does not require ink. When not in use, the tubing that leads to the bellows hangs in a special place designed to avoid kinking. The apparatus is accompanied by a set of graduated straight edges intended to facilitate computation of the results.

Sanborn Metabulator
1947.

When tested for a period of weeks by a practicing endocrinologist, the instrument gave a satisfactory performance; it was found to be well designed, compact and attractive. The investigator took occasion, however, to call to mind the variability of results obtained from basal metabolic rate determinations, even when done carefully under favorable conditions, and to urge that all determinations of metabolic rate, whether made with this machine or any other, should run not less than ten minutes.

The Council on Physical Medicine voted to include the Sanborn Metabulator 1947 in its list of accepted devices.

REBATES, KICKBACKS, COMMISSIONS AND MEDICAL ETHICS

The pride of medicine as a profession has always been its freedom from the taint of barter and trade in the sick patient. Physicians must give their wholehearted devotion to the care of the patient; no other objective must be given precedence over considerations of the patient's need. Nevertheless, the charge is made that some physicians have forgotten the ethical principles that prevail in the relationship between doctor and patient and have selected the surgeon willing to make the greatest division of fees rather than the one best suited to perform the operation. Ophthalmologists have sent the patient for lenses to opticians who returned a proportion of the fee rather than to the optician who rendered the highest quality of optical service. Occasionally orthopedic surgeons and others who utilize the work of the maker of braces, splints and elastic bandages have been willing to accept commissions from such manufacturers and have delegated the procurement of these accessories to the agency offering the largest commission rather than to the one most painstaking in production and most reasonable in price. From time to time criticism has been leveled against pharmacists who have offered commissions to physicians on the prescriptions sent to them and to the physicians who have accepted such commissions. Wherever barter and trade have insinuated their insidious and evil aspects into the practice of medicine, the quality of the service has depreciated. The morals of the physicians and the commercial agencies that deal in these unwholesome profits in this marketing of medical care have already deteriorated.

From the beginning of its entrance on the medical scene, the American Medical Association has fought this menace to the quality of medical service and to the good repute of medical practice. Resolutions have been passed by the official bodies of the Association unequivocally condemning such practices. The Judicial Council has repeatedly urged the expulsion or other action

against physicians proved to have participated in such procedures. The leaders of surgery, ophthalmology, orthopedic surgery and pharmacy have been unanimous in pointing out the extent to which such commercial considerations may break down the good repute of the specialties concerned. The American College of Surgeons adopted an oath to be taken by its fellows to the effect that they would not participate in the secret division of fees. The Principles of Ethics of the American Medical Association have declared the unethical character of such divisions—direct or indirect.

Now the development of greater complexity in medical practice and in medical relationships has introduced new factors into this problem of barter and trade. The development of roentgenology as an important medical specialty and the establishment of clinical pathologic laboratories to which physicians send patients for the making of highly technical and often costly tests have introduced new sources of rebates, kickbacks and commissions. In some communities means have been proposed for evading the condemnation of medical organizations and societies through the establishment of corporations, cooperative laboratories and roentgenologic offices of multiple ownership.

As might have been anticipated, the ultimate development was recognition by governmental agencies of the fact that the unprotected public was being exploited by such methods. The first warning and one of tremendous significance was the indictment by the Department of Justice of two manufacturing optical agencies and of a considerable number of ophthalmologists who participated in a plan which took hundreds of thousands of dollars from unknowing patients. A full report appeared in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION when the Department of Justice took this action during 1946. A popular periodical with millions of circulation has called on the medical profession to cleanse itself as it has repeatedly cleaned its own house in the past. The House of Delegates asked the Secretary of the American Medical Association to call the situation to the attention of every state and county medical society in the nation and to urge on these societies the initiation of the necessary steps toward ridding medical practice of these parasites. The Better Business Bureaus in several large communities, notably Los Angeles, have begun a campaign of enlightenment of the public regarding the extent to which these abuses prevail in their communities; they too have called on the medical profession to take the necessary steps to stop this pernicious practice.

The housecleaning has been too long delayed. Biology has proved that any living organism that tries to maintain itself in the presence of filth invariably dies. The Board of Trustees of the American Medical Association therefore calls on leaders of the medical profession in

every community in which the Association is represented to act promptly, remembering, however, the necessity for proceeding in due form by the filing of formal charges against physicians known to be participating in such methods, thus offering an opportunity for the presentation of evidence and a suitable hearing so that the innocent may not be harmed but the guilty may be properly exposed and punished.

THE CLEVELAND SESSION

The first interim session of the American Medical Association to include a meeting of the House of Delegates and a scientific program for general practitioners was held in Cleveland January 5 to 8. The total registration, which on this occasion included Fellows, members, interns and residents, was well in excess of 3,000. The minutes of the House of Delegates will indicate the important problems considered by the house. These included the adoption of an entirely new procedure for the functioning of this important representative body. The streamlining of its operation will enable the work to be carried on much more efficiently while sustaining the democratic principles on which the House of Delegates operates. Special consideration was given by the House of Delegates to such immediately pressing problems as the supply of nurses, of interns and residents, the relationship of the laboratory and roentgenology to hospital insurance practices, the place of the hospital in medical care and various plans that have been developed for extending medical care to the mass of the people and particularly to those in rural areas.

During the course of the session, the Board of Trustees distributed to the House of Delegates a complete record of the extent to which the Association has made progress in achieving the objectives of its ten point National Health Program. This report will be published soon in *THE JOURNAL*. It indicates that the American Medical Association is moving steadily forward in a systematic and organized manner to meet the needs of the American people for a wider distribution of a high quality of medical care.

The House of Delegates reaffirmed its approval of the World Medical Association and of the activities of the Board of Trustees in furthering its work.

Especially significant was the action of the House of Delegates in relation to extending still further the

rapidly expanding activities of the Association. By modification of the by-laws the subscription price of *THE JOURNAL* including fellowship was advanced to \$12 annually. Consideration was given also to the inclusion of additional sections in the scientific body of the Association.

The exhibits of this Interim Session were well up to the standard of those of the Annual Session and constitute an important portion of the graduate educational work of the American Medical Association. Simultaneously with the meetings of the House of Delegates, the section programs and the exhibits, were meetings which included a meeting of the Congress on Industrial Health conducted under the auspices of the Council on Industrial Health.

The program included many important papers, demonstrations and exhibits. Another feature of the occasion was the holding of a "Grass Roots Conference," designed to develop closer relationship between the American Medical Association, the county medical societies and the individual physicians. This conference was devoted principally to problems of the general practitioner but included also consideration of voluntary health insurance plans, hospitalization insurance plans and improvement of medical facilities in rural areas.

THE PRESIDENT'S MESSAGE

In his address to the Congress, made January 7, President Harry S. Truman stated his objectives in the field of health in the following quotations:

The greatest gap in our social security structure is the lack of adequate provision for the nation's health. We are rightly proud of the high standards of medical care we know how to provide in the United States. The fact is, however, that most of our people cannot afford to pay for the care they need.

I have often and strongly urged that this condition demands a national health program. The heart of the program must be a national system of payment for medical care based on well tried insurance principles. This great nation cannot afford to allow its citizens to suffer needlessly from the lack of proper medical care. Our ultimate aim must be a comprehensive insurance system to protect all our people equally against insecurity and ill health.

Then, following a discussion of education, he continued:

The government's programs for health, education and security are of such great importance to our democracy that we should now establish an executive department for their administration.

In the meeting of the House of Delegates last week in Cleveland, the American Medical Association, through this policy-making body, reaffirmed its point of view in opposition to compulsory sickness insurance. The House of Delegates received from the Board of Trustees a detailed statement indicating the progress that has been made toward achieving the objectives of the Association's own ten point National Health Program. Specifically, the ideals of freedom to which

President Truman referred will be most certainly maintained when the needs of the American people for medical service are met on a local community and state basis rather than on a system centrally controlled. Many millions of our citizens and their families are already protected against the costs of hospitalization and sickness by the Blue Cross Plans, the nonprofit voluntary plans for paying the costs of medical care; and the long established private insurance companies. Already the American people are far on the way toward meeting the President's standard of "a national system of payment for medical care based on well tried insurance principles." These are not, however, "compulsory." The President was apparently careful to avoid that odious word in his presentation, although he used it frequently in his previous message on health. There is not the slightest evidence that he has departed from his previous insistence on compulsory sickness insurance federally administered, as his answer to the sickness problem.

Through its National Health Program, the American Medical Association is furthering the advancement of medical science by research, by the improvement of industrial health, by better and more widely available medical education, by the expansion of preventive medical services, by the fostering of new hospitals and health centers, and in many other ways. The answer of the medical profession has not been made in words alone but in positive action.

For many years the medical profession has favored assembling and coordinating all the health functions of our national government in a single agency with an administrative head in the cabinet. Apparently the President anticipates the enactment of legislation which will combine health, education and security in one federal department. Whether or not any or all of these would suffer in such a system remains to be seen. If health is, indeed, as many a great statesman has asserted, the first consideration of government, medicine as the profession responsible for this function of our civilization should not be asked to play a subsidiary role.

THE GENERAL PRACTITIONER AWARD

At the interim session of the American Medical Association in Cleveland last week the House of Delegates awarded to Dr. Archer Chester Sudan of Kremmling, Colo., the gold medal for the general practitioner who has rendered exceptional service to his community.

Dr. Sudan left the University of Chicago, where he held a research and teaching position, in 1926 and stopped to fish in the mountain village of Kremmling, Colo.—population, 567. The story goes that the village druggist was directing him to the likeliest spot when

one of the villagers came into the drug store and said that he had heard that there was a physician in the town and that the physician was needed immediately in a little home on the outskirts of the village where there were four children with acute tonsillitis in one bed. The doctor answered this call. Kremmling, Colo., was isolated from any type of medical or hospital care. It is situated in an area where the winters are severe with heavy snowfall, low temperatures and hazardous roads over mountain passes. After remaining in Kremmling for a year, Dr. Sudan requested an extension of his leave and ultimately resigned from the staff of the University of Chicago. He remained twenty-one years in Kremmling in the general practice of medicine, serving an area

ARCHER CHESTER SUDAN, M.D.
AWARDED GENERAL PRACTITIONERS MEDAL

that was encompassed by an 80 mile radius. Many of the calls were made in a bobsled in below zero weather with aid from farmers, who carried him over short stretches of the trip. He was truly a family physician, and the families in his area looked to him as a physician and counselor.

In 1946 Dr. Sudan was made president of the Colorado State Medical Society—apparently the first time in the history of the society when a man from a completely rural area was selected for this office. Dr. Sudan is devoted to public health education; he served as a member and secretary of the school board in Kremmling for many years.

The receiver of the award was born in Sioux Falls, S. D., Aug. 15, 1892, entered the University of Chicago in 1916, received the degree of bachelor of science in

1922 and master of science in 1923 and transferred to Rush Medical College on a LaVerne Noyes Scholarship, receiving the doctor of medicine degree in 1926. He served his internship at the Denver General Hospital.

The selection of Dr. Sudan was widely hailed throughout the nation as a fine recognition of the services rendered by general practitioners in our country. When Mr. Oscar Ewing, Federal Security Administrator, presented him with the medal, Dr. Sudan replied by stating that he took it as a recognition not only of himself but of the almost two hundred other general practitioners who had been nominated for the award and also of some hundred thousand other general practitioners who so greatly serve their nation. The other two candidates nominated to the House by the Board of Trustees were Dr. Jacob T. Oliphant, Farmersburg, Ind., and Dr. W. L. Pressly, Due West, S. C. The award will be presented annually at the interim session of the American Medical Association.

PSYCHOSOMATIC MEDICINE AND "THE ART OF MEDICINE"

For fifty years deans of medical schools and speakers before graduating medical classes have stressed the never to be forgotten importance of practicing the art as well as the science of medicine. The art of medicine, they said frequently, was not taught in medical schools but gained only after long experience in practice. Knowledge of its application came only with intimate, personal knowledge of the patient and of his family background and situation in life. Because of the numerous advances in the science of medicine greatest interest was directed toward learning specific details. Both the teaching and learning processes tend to follow more easily channels of scientific fact wherein definite questions may be posed and answered rather than the abstractions of philosophy. The art of medicine has become more a historical expression than a living diagnostic and therapeutic concept.

Patients too frequently become case numbers; they are recorded as well or poorly developed and nourished persons with a chief "complaint" and one or more minor "complaints." They are considered in the case history as patients with a negative or noncontributory past, with perhaps a nondescript spouse and three to five siblings, all living and well or otherwise but in any case not relevant to the immediate illness. Patients are examined minutely, all laboratory, x-ray and other mechanical aids being used to detect the cause of the chief and minor complaints. Examinations are frequently made by several doctors, none of whom may have had opportunity to become well acquainted with the patient as a person.

In large clinics a key internist summarizes the observations and tries to determine presence or absence of

somatic disease. Positive organic lesions are expeditiously and scientifically treated, whereas those patients who do not have obvious organic disease are classified as psychoneurotic. The therapy for patients with psychoneuroses all too often consists of encouragement or injunction to refrain from some or all of their pleasures and relaxations. Such restrictions tend to complicate, rather than relieve, the patient's medical problem. Patients such as these form a fertile field for the quacks and cultists, who may be amazed at the power of simple suggestion, whether accompanied by the laying on of hands, "adjusting" the spine, or administering placebos.

Offices for diagnosis and healing of disease are increasingly concerned with patients of whom many exemplify repeated failures of application of *the art of medicine*. Meanwhile, investigators of psychologic phenomena and personality patterns have laid the foundation for the technics of psychosomatic diagnosis and therapy. These constitute essentially an attempt at systematization of the art of medicine.

In this issue of *THE JOURNAL*, page 147, Dr. Hart¹ discusses many of the methods and problems in the application of these technics. A rapidly growing volume of literature² on this subject merits the attention of every practicing physician.

Time, patience, personal knowledge of the domestic situation of the patient and an attitude of friendly interest appear to be prerequisites in the application of even the simplest technics. Patients with psychoneurotic disease may fail to show any evidence of "nervousness," but deeply buried repressions and conflicts reveal themselves as apparent, or later, actual organic disease. Heart disease, ulcer, colitis, apparent thyrotoxicosis, asthma and alcoholism are indicted as frequent expressions of these conflicts. Functional symptoms related to one organ disappear when the patient learns that the organ is not actually organically affected and appear elsewhere. Relief of symptoms through the scientific somatic approach becomes pursuit of a will o' the wisp. The psyche and the soma must be treated as a whole.³ Such technics now are required as part of the diagnostic and therapeutic armamentarium of the practicing physician. The art of medicine has returned in the scientific dress of the psychosomatic technics; these cogent reasons reemphasize the necessity for the personal doctor-patient relationship.

Current Comment

TRANSCRIPTION

"MUSIC WITH YOUR MEALS"

The Bureau of Health Education announces on page 191 a release of another series of electrical transcriptions, which brings the number of transcribed radio health program series to seventeen. The new series has been prepared with the cooperation of the Council on Foods and Nutrition, whose members furnish the materials and interviews for the recordings. This series represents a new and practical approach to the subject of food and nutrition. The programs were written in terms of situations which face the housewife, such as what to serve for breakfast, how to pack the school lunch and the everlasting problem, to eat or not to eat between meals. Vitamins have been subordinated to viands and minerals to menus. To make the entire broadcast still more palatable, harp music has been added as interludes to punctuate the discussions. These recordings are available to state and county medical societies and to other agencies, subject to medical society approval. Electrical transcriptions distributed by the Association on a loan basis in 1947 are estimated to have originated more than five thousand local broadcasts across the nation and in Hawaii and Alaska. Eight state medical associations now act as subdistributing centers for these transcriptions. Additional series planned for 1948 will be announced at approximately three months' intervals.

SENSITIZATION TO THE Hr FACTOR BY BLOOD TRANSFUSIONS

Sussman¹ reports the case of a man aged 60 who was admitted to the Beth Israel Hospital with a diagnosis of cancer of the cecum. Four months before admission the patient had received an uneventful transfusion of 500 cc. of blood. One week before admission another transfusion was begun, but it was terminated after about 400 cc. of blood had been administered because the patient contracted a chill followed by profuse sweating. Routine blood grouping revealed that the patient's blood was group B, Rh positive. Cross matching with group B, Rh-positive blood from the bank revealed questionable compatibility. Routine slide *conglutination* cross matching revealed prompt clumping of the donor's cells by the recipient's serum. Further study indicated that the patient was of group B, Rh₁Rh₂ (Hr negative). A slide sensitivity test revealed that the patient's serum clumped Rh-negative blood, Rh₂ blood, but failed to clump Rh₁ blood. This latter subsequently was shown to be Hr negative. Testing of several samples of group B, Rh₁ blood revealed agglutination of 15 of the 20 specimens tested. The 5 nonagglutinated specimens were tested with standard Hr serum and were found to be Hr negative. At the time of the initial transfusion the patient's blood had been grouped as B, Rh positive, and he had received corresponding blood. The Hr grouping of this blood was unknown. Since only 20 per cent of

random blood samples are Hr negative, it seems safe to assume that this transfusion was Hr positive. At the time of the second transfusion it was discovered that the patient was given group O, Rh-negative blood. This resulted in a moderately severe transfusion reaction. A characteristic antibody stimulation or sensitization apparently occurred at the first transfusion, manifested by an antibody-antigen reaction with the Rh-negative, Hr-positive cells of the second transfusion. Sussman argues that a third transfusion with Hr-positive cells in this sensitized patient would undoubtedly provoke a severe, if not fatal, reaction. The patient was given a transfusion of 500 cc. of group B, Rh₁Rh₂ (Hr negative) blood without reaction and with a resultant rise of hemoglobin from 8 to 9 Gm. Subsequently several transfusions of group B, Rh₁Rh₂ (Hr negative) blood were administered without any untoward reaction. The case demonstrates the danger inherent in the use of Rh-negative blood for any but Rh-negative recipients. Rapid slide testing of serum will further reduce the incidence of reactions to transfusion.

PROBLEMS OF THE AGING

Much planning for the care of the chronically ill is being done in at least eight states. Three reports have been published by the state of New York.¹ Though less than one third of persons chronically ill are aged (over 65) the group 65 and over nevertheless constitutes two thirds of the chronically ill who need care outside the home. Planning for the aged must therefore be closely correlated with planning for the chronically ill. Age 65 does not necessarily bring with it disability. The report of Chicago's recent health survey,² for instance, estimated that of Chicago-Cook County's 200,000 persons over 65 years of age, 40 per cent were active and productive and only 16,000 (8 per cent) were chronically ill. Oldsters have many problems unrelated to chronic disease. At a public hearing of the New York State Joint Legislative Committee on Problems of the Aging, held Dec. 11, 1947 in New York,³ the following matters were discussed: medical care of the elderly (geriatrics); the increasing proportion of elderly in our population; employment problems; social service to old folks; workmen's compensation and our older worker; recreational needs of the aged; housing problems; education for the elderly, and the aged in our mental institutions. Legislators may well concern themselves with the group of voters 65 years of age and over who have doubled their numbers in the last twenty-five years. Ten and one-half million people are within this age group. In New York legislators are approaching these problems on the sound basis of public hearings addressed by men and women who are experts in the field and well qualified to define the problem and suggest remedies.

ORGANIZATION SECTION

Proceedings of the Cleveland Interim Session

MINUTES OF THE INTERIM SESSION OF THE HOUSE OF DELEGATES OF THE
AMERICAN MEDICAL ASSOCIATION, HELD IN CLEVELAND, JANUARY 5-6, 1948

HOUSE OF DELEGATES

First Meeting—Monday Morning, January 5

The House of Delegates convened, in the Euclid Ballroom of the Hotel Statler, Twelfth and Euclid, Cleveland, and was called to order at 10:00 a. m. by the Speaker, Dr. R. W. Fouts.

Preliminary Report of the Reference Committee on Credentials

Dr. G. Henry Mundt, Chairman, stated that 138 delegates had registered up to the present time.

Roll Call

The Secretary called the roll and announced that a quorum was present.

General Practitioner's Award

Dr. E. L. Henderson, Chairman, Board of Trustees, presented the following statement:

"At a meeting of the Board of Trustees, following a meeting of the Council on Scientific Assembly, the Board decided that a General Practitioner's Medal should be awarded to the General Practitioner of the year."

The machinery set up for the selection of the recipient of this award was very similar to the machinery set up for selection of the recipient of the Distinguished Service Award for scientific achievement. The Executive Committee of the Section on General Practice of Medicine was selected to screen the nominations for the award and pass five names up to the Board of Trustees, in the same manner as is done in selecting the recipient of the Distinguished Service Award, and the Board of Trustees was to select three names of the five for submission to the House of Delegates, which would then vote by ballot for the recipient of the award.

Very wide publicity has been given to this matter, about the only difference between the Distinguished Service Award and the General Practitioner's Award being that anyone, any club, association, whether it is medical or otherwise, any individual in the country may send in a nomination for the General Practitioner's Award. As a result, there were approximately 180 nominations for that award. Many of these came from clubs, luncheon and women's clubs, from individuals, some old lady perhaps just scribbling a little note on a piece of paper wanting to nominate her family physician for this award. A great many of them came from medical societies. At this time the Board places in nomination the three men who have been selected to present to you, together with a biography of each, for this award: Dr. W. L. Pressly, aged 60, Due West, South Carolina; Dr. Jacob T. Oliphant, aged 60, Farmersburg, Ind., and Dr. Archer C. Sudan, aged 56, Kremmling, Colo. All of these physicians are in the general practice of medicine.

The Speaker appointed tellers who spread the ballot, and the Secretary announced that 157 delegates had been seated and that 144 votes had been cast, of which Dr. Pressly received 43, Dr. Oliphant 18 and Dr. Sudan 83. The Speaker declared Dr. Archer C. Sudan elected to receive the General Practitioner's Award since he had received the majority of the votes cast.

On motion of Dr. B. H. Minchew, Georgia, seconded by Dr. James R. McVay, Missouri, and carried, the vote was made unanimous, and Dr. E. L. Henderson, Chairman, Board of

Trustees, was requested to read the biographical statement regarding Dr. Sudan, but postponed such reading pending the receipt of the copy.

Order of Business

It was moved by Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried, that the order of business as listed in the Program for this session be followed.

Adoption of Proceedings of Atlantic City Session in 1947

The Secretary called attention to two changes in the printed proceedings of the Atlantic City Session, namely, that the name of Dr. Warren L. Allee, Missouri, should be substituted for that of Dr. A. R. McComas, Missouri, as a member of the Reference Committee on General Medical Practice, and that the heading of the third paragraph under "Introduction of Invited Guests" on page 70 should read "Address of Dr. Francisco de P. Miranda of Mexico" instead of address of Dr. Manuel Guevera Oropesa of Mexico.

The proceedings of the Atlantic City Session as printed and amended as indicated were then adopted on motion of Dr. Mather Pfeifferberger, Illinois, seconded by Dr. George W. Kosmak, New York, and carried.

Address of Speaker

The Vice Speaker, Dr. F. F. Borzell, Pennsylvania, presided while the Speaker, Dr. R. W. Fouts, read the following address: *Mr. Speaker, Members of the House of Delegates and Guests:*

Once more it is a distinct privilege and pleasure to preside over the deliberations of this distinguished body. It would appear that we are again faced with a busy session. In addition to the regular business of the House, some important interim committees will render reports. It was hoped that definitive action might be had on some of the proposed revision of the By-Laws, thereby relieving some of the load that will fall on this House at the next annual session.

The Committee to Study Revision of the Constitution and By-Laws was appointed after the session in San Francisco in July 1946. Two sessions of the House have passed and no action has been taken on this matter. The committee has met several times and has given an immense amount of study to the proposition. It would appear that much of its efforts have been directed toward editing and codification rather than making any very drastic changes. The rewriting and rearranging of the subject matter have occasioned some conflicts with the Constitution, and since the committee feels that no attempt should be made to change any of the By-Laws until the complete revision may be made, it would appear that discussion or consideration of any changes would be inadvisable at this time. You have no doubt noted that some rather significant changes are being proposed by the Special Committee to Expedite the Work of the House of Delegates. It is hoped that thorough consideration be given this report and that any action taken will be consistent with the maintenance of proper decorum, and the dignity befitting a legislative body that is without a peer.

It seems advisable to your Speaker to request the appointment of three special reference committees: Executive Session, General Medical Practice, and Medical Service. Is this request granted?

On motion of Dr. E. S. Hamilton, Illinois, seconded by several and carried, the Speaker was granted permission to nominate members for the three additional reference committees which he requested.

Reference Committees

The personnel of all reference committees confirmed by the House on motion of Dr. Walter E. Vest, West Virginia, seconded by Dr. L. J. Kosminsky, Arkansas, and carried, is as follows:

SECTIONS AND SECTION WORK

Walter Phippen, Massachusetts, Chairman.	George A. Unfug, Colorado.
Charles T. Stone, Section on Internal Medicine.	Val H. Fuchs, Louisiana.
	Grover C. Penberthy, Section on Surgery, General and Abdominal.

RULES AND ORDER OF BUSINESS

Thomas K. Lewis, New Jersey, Chairman.	H. Russell Brown, South Dakota.
Harry Aranow, New York.	Morton D. Willcutts, U. S. Navy.
Charles R. Rountree, Oklahoma.	

MEDICAL EDUCATION

Creighton Barker, Connecticut, Chairman.	J. Morrison Hutcheson, Virginia.
A. A. Walker, Alabama.	Alfred T. Gundry, Maryland.
	Robert E. Schluter, Missouri.

LEGISLATION AND PUBLIC RELATIONS

William Bates, Pennsylvania, Chairman.	Karl S. J. Hohlen, Nebraska.
Claude R. Keyport, Michigan.	D. A. Rhinehart, Arkansas.
Allen H. Bunce, Georgia.	

HYGIENE AND PUBLIC HEALTH

William L. Estes, Jr., Pennsylvania, Chairman.	James A. Crabtree, U. S. Public Health Service.
Robertson Ward, California.	W. P. Anderton, New York.
James P. Wall, Mississippi.	

AMENDMENTS TO THE CONSTITUTION AND BY-LAWS

W. R. Coventry, Minnesota, Chairman.	John J. Masterson, New York.
H. B. Woolley, Idaho.	J. D. Hamer, Arizona.
F. J. L. Blasingame, Texas.	

REPORTS OF OFFICERS

Deering G. Smith, New Hampshire.	Clifford C. Sherburne, Ohio.
Warren L. Allee, Missouri.	Benjamin H. Minchew, Georgia.
John W. Green, California.	

REPORTS OF BOARD OF TRUSTEES AND SECRETARY

O. W. H. Mitchell, New York, Chairman.	E. H. Cary, Texas.
H. G. Hamer, Indiana.	Robert H. Hayes, Illinois.
	J. B. Lukens, Kentucky.

CREDENTIALS

G. Henry Mundt, Illinois, Chairman.	Charles F. Strosnider, North Carolina.
Carl A. Lincke, Ohio.	Raymond F. Peterson, Montana.
H. B. Everett, Tennessee.	

MISCELLANEOUS BUSINESS

Edgar P. McNamee, Ohio, Chairman.	L. W. Larson, Section on Pathology and Physiology.
Floyd S. Winslow, New York.	B. R. Kirklin, Section on Radiology.
Homer L. Pearson Jr., Florida.	

EXECUTIVE SESSION

Alfred F. R. Andresen, New York, Chairman.	Fred H. Muller, Illinois.
Stephen E. Gavin, Wisconsin.	James L. Whitehill, Pennsylvania.
Charles E. Mongan, Massachusetts.	George P. Johnston, Wyoming.
Ralph B. Eusden, California.	Hugh P. Smith, South Carolina.

GENERAL MEDICAL PRACTICE

E. V. Askey, California, Chairman.	Wilbur C. Davison, North Carolina.
Howard E. Griffin, Section on General Practice of Medicine.	Philip W. Morgan, Kansas.
Gerald V. Coughlan, Iowa.	Theodore H. Harwood, Vermont.
James Beebe, Delaware.	F. S. Crockett, Indiana.

MEDICAL SERVICE

Edwin S. Hamilton, Illinois, Chairman.	Ralph T. B. Todd, New York.
Raymond L. Zech, Washington.	William Weston, Section on Pediatrics.
C. D. Conklin, District of Columbia.	Edward H. McLean, Oregon.
	Ivan Fawcett, West Virginia.

TELLERS

Joseph F. Londrigan, New Jersey, Chairman.	Thomas A. Foster, Maine.
James P. Kerby, Utah.	William W. Will, Minnesota.

SERGEANTS AT ARMS

J. Stanley Kenney, New York, Chairman.	Wyman D. Barrett, Michigan.
	John A. Fuller, Nevada.

Address of President, Dr. E. L. Bortz

The Speaker resumed the chair and presented Dr. E. L. Bortz, President, who delivered the following address, which was referred to the Reference Committee on Reports of Officers: *Mr. Speaker and Members of the House:*

Since the Centennial Celebration of the American Medical Association in Atlantic City last June, as President of the Association I have had an opportunity to survey a good many of the activities of our organization, to confer with officials and other representatives, and to study in greater detail the work of certain of the Councils and Committees. In addition to this, many of you have extended invitations to me to visit with various state and county societies and other medical organizations. For these generous invitations I am deeply grateful. Please understand that it is physically impossible to accept more than a certain number of speaking engagements and do justice to them. Elevation to the Presidency of this Association, in addition to the high honor which it represents, carries a great responsibility and obligation. In full realization of these facts I have endeavored to interpret, as I saw them, the objectives of the Association and to inform public audiences of the important activities in which our Association is engaged in behalf of a higher level of health for our nation.

Six months ago certain recommendations were made to this House. To the Interim Session of the House of Delegates has been added a scientific program which should be of real value to general practitioners. Medical science is extending its frontiers. Leaders in various fields have collaborated with officials of the American Medical Association in bringing to its membership discussions concerning the etiology, diagnosis and treatment of the common and rare maladies that afflict our fellow men. The Council on Scientific Assembly has drawn up an excellent scientific program for this Interim Session of the House. The American Medical Association is the parent body for the general practitioners, the family physicians of the nation. As such it merits their loyalty and active support. If our Association does not completely meet the needs of the general practitioners, it nevertheless furnishes the best forum for the discussion of their problems, and it has the personnel and experience to meet them from time to time. Participation in the activities of the American Medical Association and the support of its policies are necessary for the welfare of the medical profession as a whole.

Before Cleveland was designated as the meeting place a number of other cities were considered. Even with a smaller attendance at the Interim Session, housing space required for such a large meeting is a serious problem. Rest assured that the officials of the Association are doing their level best to meet this problem from time to time.

Immediately after the House approved the recommendation of closer affiliation of medical students the Board of Trustees took the matter under advisement. Certain alterations in the By-Laws will be necessary. These will be presented to you with the hope that in the not too distant future a plan for student affiliate membership to bring third and fourth year medical students, and perhaps the students of the first and second years also, into the membership will be created. It would be helpful were state and county societies to take up this problem locally where medical schools are established. Consideration will be given for worthy papers by students for inclusion in THE JOURNAL.

PUBLIC RELATIONS

The Board has been carefully studying the various phases of the public relations problem. In many of its activities the public relations aspects of medical practice have represented one of the most important activities over a period of many years. The Bureau of Health Education, the Committee on Rural Medical Service, the Council on Medical Service, the Woman's Auxiliary and other important instruments of the Association have been active in many ways to keep the public informed of medical advances and of the manifold measures which organized medicine is promoting for the public welfare. Public relations in essence is much more than the appointment of a counsel. A certain responsibility devolves on each doctor and employee of the profession to interpret correctly its functions in terms of public benefit.

THE HANDBOOK

The Secretary, Dr. George F. Lull, assigned Dr. Austin Smith and others the work of writing up a modern handbook which was in accord with the recommendations of the House last June. This attractive little volume will be ready for distribution in the near future. I would urge that members of the Association critically read through its pages and then familiarize themselves with the activities of the various departments at headquarters. No one can appreciate the great amount of constructive work which is being carried on by the headquarters' staff in behalf of a higher quality of medical care for the American people. In the three major fields—medical education, health education of the public and research—the staff is blazing new trails and extending medical knowledge to all parts of the country. If the American public were cognizant of the work which the American Medical Association is carrying on in so many various fields there would be fewer discussions of the role which our Association is playing in behalf of a higher quality of medical care.

THE WOMAN'S AUXILIARY

A special credit should be paid to the Woman's Auxiliary. Under the leadership of its charming President, Mrs. Eustace Allen of Georgia, and a corps of excellent committeewomen, the Auxiliary is now beginning to assume its rightful role. It represents probably our most effective instrument in the field of public relations, which, unfortunately, has been the most neglected. As with all of us, the first need for the members of the Auxiliary is to be basically well informed of the issues at stake. All of us should obtain from the various Councils and Officers of the Association the recent factual material which carries controversial issues facing medicine today. One renders our profession a disservice when appearing before a lay group if one is not sufficiently informed. Therefore, the first responsibility is to have a clear conception of our job and how we mean to carry it on.

THE NURSING PROBLEM

Our Committee on Nursing Problems, headed by Dr. Thomas P. Murdock of Connecticut, has quietly but meticulously been carrying on a very careful investigation. The committee has been in contact with representatives of other groups, including nursing organizations, hospital administrators, specialized organizations representing surgeons, pediatricians, radiologists and other groups. One can predict a contribution of value from this active committee.

THE COUNCIL ON NATIONAL EMERGENCY MEDICAL SERVICE

The Council on National Emergency Medical Service has recently become active and has had conferences with several officials of governmental agencies and civilian groups. It is high time that organized medicine and its various subgroups play a larger role in preparing the members of the profession and allied groups for rendering an emergency medical service in time of need. The development of atomic energy as an industrial project immediately forces on the medical profession the necessity of a clear understanding of the hazards which attend proximity to radioactive substances, which are now being elaborated in great quantity. An appreciation of these dangers and an understanding of protection against them and also of management of casualties represent one of the important challenges facing medicine. The Council, in collaboration with the Council on Physical Medicine and that on Industrial Health, hopes to stimulate the interest in this field at all levels and in all sections of the country.

I should like to introduce at this point a statement just received from Dr. Shields Warren, Medical Consultant to the Atomic Energy Commission:

The increasing use of atomic energy and of its outstanding peace time products, the radioactive isotopes, constitutes a challenge to the medical profession. The radioactive isotopes are the most important development in research since the invention of the microscope. They promise to unfold new techniques that will demand the highest degree of scientific imagination and skill for full exploitation. The responsibility of the new fields is clear and pressing.

As in any new field, hazards as well as benefits exist. Potential dangers to investigators, their patients and the general public from the use of radioactive isotopes dictate that the medical profession is also responsible for the prevention and recognition of these dangers.

The unprecedented scale of derangements that would result from an atomic explosion presents a new and vital responsibility to the medical profession. Plans for medical organization to effectively handle these aspects of such explosion should be in existence and such plans should be at a continuing high level of readiness.

The Atomic Energy Commission is desirous that the medical profession shall explore all possible avenues by which the beneficial effect of atomic energy may be used to aid mankind and that the medical profession shall take the necessary measures to protect mankind against radiation and other hazards which may exist in the field of atomic energy.

At a time of international disequilibrium and great social unrest the medical profession is peculiarly vulnerable, since as a whole the doctors of the nation are not prepared, nor are hospitals or nurses, to care for large numbers of casualties if an incident precipitated a major catastrophe in the near future. This is a charge which organized medicine cannot escape. It is an unpleasant responsibility that must be acknowledged and dealt with. Default of leadership on the part of the American Medical Association may result in disaster for the civilian population unless military medical authorities take over. This would result if organized medicine does not accept its responsibility.

MEDICINE ON THE MARCH

While the physician today is a more effective agent in behalf of the health of his patients and in the support of public health measures than at all previous time in the history of our country, an additional responsibility now must be assumed. We must accept leadership for the consideration of various plans that will furnish acceptable medical care to those members of communities who are, for various reasons, at one time or another unable completely to meet the financial demands for such care. No answer is yet available for all the variations of this problem. In the meantime the experimental method should be followed under local and controlled conditions. Pilot studies can be carried on in communities as in laboratories over a span of several years. From time to time an accounting of accomplishments, and a reconsideration of detriments, should aid in the final solution of the problem. Obviously no one plan can be a solution for all portions of the population of our great nation. Flexibility and adjustment to community needs is in order. It should always be kept in mind that compulsion is in order. It should always be kept in mind that compulsion is an odious term, and taxation is not ordinarily interpreted as insurance. In setting up any plan therefore it is important that accurately descriptive terms should be employed by all concerned. As our Congress is in session it is our responsibility to see that the folks back home instruct their representatives concerning the importance of maintaining the democratic approach to the solution of our social problems. Let's be awake to the challenge and find in it a means to a high level of medical service.

PROPOSED NEW HOME

This House approved the suggestion that the Board of Trustees take under advisement a building program. The Board of Trustees has been in communication with an architect. Tentative plans have been discussed. It is hoped that the aesthetic aspect of future construction will not be neglected. Medicine is an art as well as a science. It has a cultural and an aesthetic quality. This should be reflected when possible in its building program. Indifference to the artistic qualities that may be built into a new edifice should be avoided. One can have beauty as well as utility. It is hoped that this phase of the building program will not be entirely overlooked.

A DISTINGUISHED HONOR

On Dec. 16, 1947, the American Pharmaceutical Manufacturers' Association bestowed its Scientific Award on the American Medical Association in recognition of the services which were rendered in behalf of service to the public and medical research. At a brilliant ceremony in New York City the American Pharmaceutical Manufacturers' Association bestowed this award, which was accepted by the President-Elect, Dr. R. L. Sensenich. This honor represents a recognition from one of our great allies in the field of medicine which reflects credit on all members of our organization. The Board of Trustees and other officials were present in person at this ceremony.

1948

Organized medicine enters the new year with great promise. The officials of our organization have its work well in hand. Each council and committee is actively engaged with the increasing responsibilities of the Association. The major objectives of medical education, education of the public, and the furtherance of medical research are being well served. As was stated before, our Association has never played a role of such commanding importance in helping to shape the destinies of the health of the nation as it is doing at the present time. Much has been accomplished, but much more remains to be done. With teamwork and loyalty, and an optimistic attitude, the membership may look forward hopefully to 1948 as one of the big years for organized medicine, and, of even greater importance, through its activities to a more healthful nation.

Presentation of the President-Elect, Dr. R. L. Sensenich

The Speaker presented to the House the President-Elect, Dr. R. L. Sensenich, South Bend, Ind., who spoke as follows: *Mr. Speaker and Members of the House:*

I have so recently been honored by this body, having been selected from the working group, and as I have the greatest respect for the recommendations of your Committee to Expedite Work of the House, it would not be fitting that I take any of your time in discussing some of those things which might be of interest. Some other time perhaps I shall do that.

I am tremendously impressed, after having been a member of the House some years, having served ten years on the Board of Trustees and having had an opportunity to see the picture in its broadest dimensions, with the expanding area, we will say, in which medicine and medical organizations properly should be interested.

At no time in the world's history, as the President pointed out a moment ago, have there been the opportunities for medical leadership, the opportunities to accomplish something for the welfare of the public, that are now offered.

The situation, as it is the world over, has presented so many new problems but, at the same time, so many new opportunities for helpfulness. You are the governing body of the world's largest and most influential medical organization. You have opportunities for a tremendously constructive job, and I am sure that you are capable of doing that. Along with that comes the opportunity for leadership that no medical organization in the world has ever had.

I am sure that your deliberations, your thinking and your planning will be reflected to the tremendous advantage not only of our own people but of those all over the world. Your Chairman of the Board of Trustees will tell you in a little while about some of the things that are being done with the World Medical Association. It might be easy to dismiss that, in a moment by saying, "Well, that is the world. We are interested in America." As it is today, America cannot be entirely neglectful of the things that are happening in other parts of the world. You are now in position to take that leadership and you are being well received. I am sure that that work should continue in a constructive fashion.

Anything that I can do, anything in which my humble efforts may be helpful in carrying out the things which you wish me to do, I shall be very happy to do. Thank you very much.

Report of Board of Trustees

BIOGRAPHY OF DR. ARCHER C. SUDAN, KREMMLING, COLO.

Dr. E. L. Henderson, Chairman, Board of Trustees, read the following short biographic report of Dr. Sudan, adding that in setting up the machinery for this award, it was decided by the Board of Trustees that no past general officer or present member of the House of Delegates would be eligible for this award.

Dr. Archer Chester Sudan, following research and teaching at the University of Chicago in 1926, stopped in Kremmling, Colo., a community of slightly over 500 persons without any physicians or facilities for medical care. Following a year's service to the community, he resigned his position in the University of Chicago and for twenty-one years engaged in the general practice of medicine in Kremmling and in an 80 mile

radius surrounding the village. In 1946 he became president of the Colorado State Medical Society. He has participated in education of the public for better health, and has been member and secretary of the school board.

ASSOCIATION FINANCES

During recent years the Board of Trustees has become seriously concerned over the finances of the Association. The activities have multiplied and the costs of operation have increased tremendously. The Board of Trustees believes, therefore, that a report should be made at this time to the House of Delegates.

For the calendar year that has just closed, there is an indicated loss of approximately \$170,495; even with reductions that have been made in a number of budgets, the budgets for 1948 exceed apparent income by over \$100,000. There are many reasons for this increase in expenditures over previous years. As an example, the Board submits the cost of printing an individual copy of *THE JOURNAL*: In 1939 a *JOURNAL* containing 128 pages cost, for labor, paper, ink, etc., 8.5 cents per copy; in 1947 a *JOURNAL* of the same size cost 12.6 cents per copy, which does not include the cost of mailing and handling after printing.

Not only have wages increased, both in the factory and in the office, but, on account of additional activities of the Association, more employees have been necessary. As an example, on Jan. 1, 1947, 638 persons were in the employ of the Association, while on Aug. 1, 1947, 707 persons were employed. About one third of the employees are working in the printing department, while the other two thirds are employed in the offices of the Association.

A few items may be taken as examples of the increased cost of operation in 1947 over 1946: Paper stock in 1946 cost \$334,610, and in 1947 approximately the same amount and quality of paper cost \$460,000. The cost of electrotypes and engravings increased \$10,000; factory and mailing supplies, \$9,000; ink, \$9,000; second-class postage, \$10,000; other postage, \$10,000; telephone calls and telegrams, \$3,000; power and light, \$2,000; building maintenance, \$10,000.

These items are quoted so that the House of Delegates will have full knowledge of the financial structure. Advertising rates in the Association's periodicals have been substantially increased. It therefore remains for the Association either to find some other method of increasing revenue or to curtail activities.

HOSPITALS AND THE PRACTICE OF MEDICINE

The following report of a committee of the Board is presented:

The practice of medicine by hospitals has been a moot subject for many years. Year after year medical societies, including the American Medical Association, have passed resolutions condemning the system whereby a hospital exploits the services of a physician. This has applied particularly to the four specialties of anesthesiology, pathology, radiology and physical therapy.

The passing of these resolutions has not accomplished a completely satisfactory solution of the problem. A great deal of further study and experimentation must be had to work out a satisfactory solution of this vexing problem.

It would appear that at least we should insist on the following: (1) recognition that the specialties of pathology, radiology, anesthesiology and physical therapy are the practice of medicine; (2) all specialists in a hospital should be under the jurisdiction of the medical board; (3) all specialists should be on the staff of the hospital and be represented on the medical board; (4) conditions of employment will vary locally and they must have the approval of the medical board of the hospital whose responsibility it should be to see that these provisions are carried out; (5) the interests of the general public should be paramount and local conditions must be taken into consideration; (6) there must be cooperative understandings with the hospitals and specialists groups, and (7) it is recommended that the House of Delegates request the Board of Trustees to appoint a committee to study the various resolutions passed previously by the House and that this committee be directed to arrange conferences with the hospital associations and the various specialist societies, in order that a solution may be worked out which will be fair to all parties and redound to the benefit of the public.

It is further recommended that the report of this committee, when prepared, be referred by the Board of Trustees to the Judicial Council for such revision of the Principles of Medical Ethics as may be indicated by the content of that report.

LOUIS H. BAUER, Chairman.
ROY W. FOUTS.
JAMES R. MILLER.

THE WORLD MEDICAL ASSOCIATION

Four representatives of the American Medical Association attended the organization of the World Medical Association in Paris in September. Dr. E. L. Henderson and Dr. L. H. Bauer attended as delegates, and Dr. E. E. Irons and Dr. R. L. Sen-senich as alternate delegates.

Forty-eight nations were represented, covering the greater part of the world.

The aims of the Association as defined in its Constitution are: (1) to promote closer ties among the national medical organizations and among the doctors of the world by personal contact and all other means possible; (2) to maintain the honor and protect the interests of the medical profession; (3) to study and report on the professional problems which confront the medical profession in the different countries; (4) to organize an exchange of information on matters of interest to the medical profession; (5) to establish relations with and to present the views of the medical profession to the World Health Organization, U. N. E. S. C. O., and other appropriate bodies; (6) to assist all peoples of the world to attain the highest possible level of health, and (7) to promote world peace.

The Association is organized into a General Assembly, consisting of two delegates from each national medical association and a General Council, consisting of the President, the President-Elect, the Treasurer and ten elective members. The President is to come from the country in which the General Assembly meets.

The President is from France, the President-Elect from Czecho-Slovakia, the Treasurer from Switzerland and the members of the Council from England, Sweden, France, Spain, Austria, India, China, Cuba, Canada and the United States.

As it was evident that the income from dues would be insufficient to make the organization effective, your delegates offered to provide \$50,000 a year for five years, to be raised by voluntary subscription from industry, medical organizations and individual physicians, in order to put the Association on its feet. This money is to be spent under the auspices of a supporting United States committee. There were certain provisions which had to be agreed to by the Association before the money would be available. These provisos were accepted. The important one was that the headquarters and general secretariat would have to be located in North America. It has since been decided that the headquarters will be in New York City.

The temporary Secretary is Dr. Charles Hill of Great Britain. The permanent Secretary is yet to be selected. There are to be three assistant secretaries, one English speaking, one French speaking, and one Spanish speaking, as these three languages are the official ones of the Association.

The Association is to publish a *Bulletin* at stated intervals. Two surveys are already under way, one concerning the status of the physician and medical practice in all countries, and the other concerning medical education and licensing in all countries.

The Association condemned medical war crimes, urged the adoption of an oath to be taken by all prospective physicians forewarning such practices and decided not to admit the German Medical Syndicate to membership until it had repudiated the war crimes committed by its members, had expelled them and had given assurance that such crimes would not occur in the future.

Many of the countries need help and many do not have strong medical associations. We aim to assist them to help themselves.

This new Association, born on September 18, 1947, has great potentialities. If the doctors of the world cannot get together, it is doubtful if anyone can. It may well be that this organization will prove to be the first step toward a better understanding among nations, and if so it will be well worth while.

The Speaker referred the report to the Reference Committee on Reports of Board of Trustees and Secretary, except the

portion of the report dealing with hospitals and the practice of medicine, which was referred to the Reference Committee on Miscellaneous Topics, and except the portion of the report dealing with the World Medical Association, which was referred to the Reference Committee on Legislation and Public Relations.

SUPPLEMENT TO REPORT OF BOARD OF TRUSTEES RESOLUTION REQUESTING AMENDMENT TO BY-LAWS TO INCREASE FELLOWSHIP DUES

Dr. Allen H. Bunce, Georgia, presented the following resolution as a supplement to the report of the Board of Trustees, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary:

WHEREAS, The Board of Trustees has presented to the House of Delegates information concerning the income and expenditures of the American Medical Association leading to the belief that an increase in income is necessary if the Association is to carry out the many responsibilities placed on it by the House of Delegates; and

WHEREAS, The American Medical Association has within recent years expanded greatly its activities by the establishment of councils, committees and bureaus and departments charged with new functions; and

WHEREAS, The chief income of the American Medical Association derives from the subscriptions to its various publications, including chiefly *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, and

WHEREAS, Chapter 18 of the By-Laws of the American Medical Association was last amended in 1929 so that it reads: "The annual Fellowship dues and the subscription price of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* shall be fixed by the Board of Trustees, and the same shall be payable in advance, on the first day of January of each year, provided that the annual dues shall not exceed \$8, and provided that the amount of the same shall be announced in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* not later than November 1 of each year"; therefore be it

Resolved, That this House of Delegates amend Chapter 18, "Annual Fellowship Dues," to read: Except with respect to the year 1948, the annual Fellowship dues and the subscription price of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* shall be fixed by the Board of Trustees and the same shall be payable in advance on the first day of January in each year provided that the annual dues shall not exceed \$12, and provided that the amount of the same shall be announced in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* not later than November 1 of each year. For the year 1948 such dues and subscription price of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* shall be \$12 and shall be payable in advance not later than April 1 of that year, provided that a notice of the said dues and subscription price of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* set by the adoption of this amendment is given each Fellow prior to April 1, either in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* or by mail as circumstances may indicate.

Motion Commending Delegates to World Medical Association

It was moved by Dr. John W. Cline, California, seconded by Dr. George W. Kosmak, New York, and carried, that the delegates representing the American Medical Association at the World Medical Association be commended for their wisdom, initiative and foresight in furthering this objective.

Report of Committee to Expedite Work of House of Delegates

Dr. James R. Reuling, New York, presented the Report of the Committee to Expedite the Work of the House of Delegates as published in the program, which was referred to the Reference Committee on Rules and Order of Business.

Report of Committee on Nursing Problems

Dr. Thomas P. Murdock, Chairman, presented the following report, which was referred to the Reference Committee on Medical Education:

Mr. Speaker and Gentlemen of the House of Delegates:

At the annual session in Atlantic City in June 1947 Dr. E. L. Bortz in his presidential address to the House of Delegates recommended the appointment of a committee to study the nursing problem. The recommendation was approved by the reference committee and by the House of Delegates. In due time it was cleared by the Board of Trustees, and the President appointed the committee in July 1947.

The members of the original committee were Dr. Lester Dragstedt, Brigadier General Warren Draper, Dr. Wingate Johnson, Dr. Donald Smelzer and Dr. T. P. Murdock. Dr. Dragstedt refused appointment and Dr. Wingate Johnson resigned after election to the Board of Trustees. Dr. Howard K. Gray was appointed to replace Dr. Dragstedt and Dr. W. P. Parsons to replace Dr. Johnson.

The committee held its first meeting in New York on Sept. 3, 1947. At this meeting the committee organized and reviewed exhaustively all of the correspondence and available literature, including the results of the poll of the American Surgical Association and the reports of studies of the American College of Surgeons.

On Oct. 16, 1947 a subcommittee met in New York City with representatives of the various nurses organizations. On October 17, 1947 the committee met in Chicago with representatives of the American Hospital Association and the American College of Surgeons.

On November 21 and 22, 1947 the committee met at the headquarters of the American Medical Association with representatives of the nursing organizations, the American College of Surgeons and the American Hospital Association.

The study is being conducted along three lines: (1) immediate relief; (2) the future training courses to be recommended for various grades of nurses; (3) the economic conditions.

Regarding the first, attempts are being made to bring out of retirement as many nurses as possible, to fit immediately into the picture as many practical nurses as possible, to train on the job attendants and to try to see to it that work now improperly assigned to nurses will be done by others.

Regarding the second, editorials are to appear or have appeared in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, *Hygia* and every state and county journal in the United States stimulating the doctors to aid in recruitment of student nurses. Radio plays are being prepared by Dr. W. W. Bauer to stimulate young ladies to enter the nursing profession. The study is going forward to plan a grade of nurse, below the present day professional nurse, to do bedside nursing under the supervision of the professional nurse. This phase has not been completed but there is general agreement of all groups that this can be accomplished. There is also the hope that uniform standards of training can be established for this group.

Covering the third or economic phase, studies are being pursued to include nurses under the social security act. Retirement plans for nurses are being investigated. The question of attempting to tie in the cost of nursing with prepayment voluntary hospital and medical care plans and with old line insurance companies is being investigated. With this last phase the committee somewhat pessimistic as to its possibilities due to excessive costs.

The committee expresses its thanks to the President, Dr. E. L. Bortz, the Board of Trustees, Dr. George F. Lull, Dr. Morris Fishbein and the headquarters staff for their help. The representatives of the American College of Surgeons have been most helpful. The committee at all times has had the generous cooperation of the representatives of the American Hospital Association, particularly Mr. George Bugbee and Dr. Hugo Hullerman.

The committee is pleased to report the very great aid given by the representatives of the nursing organizations. It feels that they are contributing a great deal to the study, are anxious to have the problem solved and have very intimate knowledge of the difficulties of the situation. Their willingness to aid, their tolerance and suggestions have been a source of comfort to the committee.

At this point your committee wishes to bring out a suggestion originating with the American Hospital Association. This is for a continuing conference committee to be made up of representatives of the American Hospital Association, the American Nurses Association and the American Medical Association. The purpose of this committee is to study problems that are common to all. Your committee recommends that a committee of five be appointed for this purpose.

Mr. Speaker, this must of necessity be considered only as a report of progress excepting that part having to do with the appointment of a permanent conference committee, which it is hoped will be acted on at this session.

Respectfully submitted,
T. P. MURDOCK, Chairman.
WARREN DRAPER.
HOWARD K. GRAY.
W. P. PARSONS.
DONALD SMELZER.

Report of Committee on Rural Medical Service

Dr. F. S. Crockett, Chairman, presented a handbook of reports of activities during the past year of forty-five of the forty-eight states where the state medical committee on rural medical service has carried on its activities, a copy of which was distributed to each delegate and served as a report of the committee. This was referred to the Reference Committee on Medical Service.

Report of Council on Scientific Assembly

Dr. Henry R. Viets, Chairman, presented the following report, and the portion of the report dealing with the Section on Diseases of the Chest was referred to the Reference Committee on Amendments to the Constitution and By-Laws:

To the Members of the House of Delegates of the American Medical Association:

The Council on Scientific Assembly has met three times since the 1947 Annual Session in Atlantic City, once on September 4 and again on October 18, both meetings being held in Chicago, and a third meeting in Cleveland on Jan. 4, 1948.

The Council offers the Scientific Program for the Cleveland Interim Session as part of its report.

SECTION ON DISEASES OF THE CHEST

The House of Delegates at the 1947 Atlantic City Session, on the last day of the meeting, approved the establishment of a new Section on Diseases of the Chest. The By-Laws were not changed at this meeting because action could not be taken at that time; a proposed amendment, needed to create a new Section, must lie over for twenty-four hours. Because the Section on Diseases of the Chest could not function as a Section in 1948, the Council on Scientific Assembly voted to devote one session in the Section on Miscellaneous Topics at the 1948 Annual Session in Chicago to a program on Diseases of the Chest.

The approval of this new Section by the House did not conform to the procedure set forth in the By-Laws, although the House had the right to create the section under the Constitution of the American Medical Association.

The Council is disturbed by the procedure adopted by the House in creating the new Section on Diseases of the Chest before the Council had given full consideration to the application and had made its report to the House. The Council is charged in the By-Laws not only with setting up the scientific programs but "to consider at first hand applications for new sections, or for changes in existing sections, and report to the House of Delegates." From the point of view of the Council, therefore, the action by the House in 1947 in establishing a section without the Council's considering "at first hand" the application, disturbs the efficient functioning of the organization of the American Medical Association, particularly as applications for other sections were pending at that time and were being given orderly recognition by the method established by the By-Laws.

SECTION ON MISCELLANEOUS TOPICS

The Council also voted to grant a session on Allergy and one on the History of Medicine in the Section on Miscellaneous Topics at the 1948 Annual Session, in addition to a Session on Diseases of the Chest. A chairman and secretary for each session was appointed by the Council as provided for by the By-Laws.

A request for a session on Legal Medicine in the Section on Miscellaneous Topics was received. The request could not be granted in view of the fact that the three sessions had already been assigned by the Council on Scientific Assembly. Dr. Moritz was urged to offer a group of papers on Legal Medicine to the Council for consideration in the program of the General Scientific Meetings at the 1948 Annual Session and was asked to give consideration to the presentation of papers of a similar nature before the Section on the General Practice of Medicine or before the Section on Preventive and Industrial Medicine and Public Health or the Section on Pathology and Physiology or at a joint meeting of two sections.

ANNUAL CONFERENCE OF SECTION SECRETARIES

The Annual Conference of Section Secretaries with the Council on Scientific Assembly was held on Oct. 18, 1947, and preparations were made for the usual scheduled section meetings for the 1948 Annual Session.

CENTENNIAL CELEBRATIONS OF SECTIONS

The Council took cognizance of the resolution adopted by the House of Delegates at the 1947 Atlantic City Session on sections celebrating their centennials. As the first centennial will not occur for ten years, no definite action was taken by the Council at this time.

PHYSICAL MEDICINE

An application by a representative group of physicians was presented to the Council for the establishment of a Section on Physical Medicine in the American Medical Association. After due consideration it was voted to defer action on this application.

SECTION REORGANIZATION

The Council continued its studies on section reorganization and voted to request the House of Delegates for permission to have a joint meeting with the Committee to Study Revision of Constitution and By-Laws, to consider in particular the functions of the Scientific Assembly.

Respectfully submitted,

HENRY R. VIETS, Chairman.	
CHARLES H. PHIFER.	
LEONARD W. LARSON.	
STANLEY P. REIMANN.	
LUKE B. JACKSON.	
R. L. SENSENICH, President-Elect.	} ex officio
MORRIS FISHBURN,	
GEORGE F. LULL, Secretary.	

Report of Council on Medical Service

Dr. James R. McVay, Chairman, presented the following Report of the Council on Medical Service, which was referred to the Reference Committee on Medical Service:

Community leadership in health problems by county medical societies and state medical associations will be the goal of the Council on Medical Service for 1948.

Since the June Session of the House of Delegates the Council on Medical Service has carried on its regular activities and has begun study on various matters referred to it by the House. In addition, the Council has found it advisable to look back on its original functions and appraise some of the Council's objectives and the methods used to reach those objectives. At this time the Council will report progress with reference to particular activities and studies. The Council will submit a complete report at the regular annual session of the House of Delegates in June 1948.

PROFESSIONAL RELATIONSHIPS

The task of informing the medical profession of activities and trends in the broad field of medical care is, in itself, of sufficient importance and magnitude to require much of the time and energies of the Council and its staff. The Council feels it has broken the ground, or paved the way, to a better understanding between the constituent associations and component societies and the American Medical Association, and that through this better understanding much good will come.

REGIONAL CONFERENCES

The sixteen regional conferences which the Council has sponsored during the past four years have provided a medium for exchange of information and of ideas. In the past few months the Council either sponsored or participated in five conferences—in Atlanta, in New Orleans, in Philadelphia, in St. Paul and in Cleveland. Several different types of conferences are being tried. In Atlanta, representatives of important lay groups were given prominence in the one day program; in New Orleans, the conference was increased to two days with each of the four half days devoted to a round table discussion of a particular subject suggested by the participating states, and in Cleveland emphasis

was placed on the services which the American Medical Association is prepared to render to medical societies and to member physicians. Conferences have been arranged for this spring in the Northwest and in the Rocky Mountain areas.

It has been evident to the Council that different types of conferences are effective in different areas. We propose to continue experimenting with various approaches in our regional conferences and ultimately hope to arrive at several workable methods for exchanging information and ideas and for translating these into action which will improve medical services to the American people.

THE NEWS LETTER

The News Letter of the Council continues to be a source of information to over 3,500 physicians. The distribution has been limited to this figure only because funds are lacking to supply it to all who would like to be on the mailing list.

The News Letter reports on many activities in as brief a manner as is possible. This type of reporting is essential to continued readership, and the regular monthly letters will retain this style.

At the same time the Council believes that there are many programs and trends in medical service that need reporting in complete detail. Several special News Letters have been issued to meet this need. An example is the letter devoted to Cancer Control Programs.

The Council is considering also a quarterly publication on socio-economic matters. Details of many medical service programs carried on by medical societies could be presented in such a publication. An example of a problem needing detailed treatment is indigent medical care. The quarterly publication could show how this problem is approached in cities or counties where successful programs are in operation. Details on many phases of medical service in which medical societies have been successful would make excellent reference material for other medical societies and would provide a vast amount of data in support of the Ten Point National Health Program of the American Medical Association.

V. A. HOME TOWN MEDICAL CARE CONFERENCE

The House of Delegates at its June session authorized the Council to sponsor a conference of state medical association representatives to discuss the Veterans Administration Home Town Medical Care Program. The conference, held November 6, was attended by General Paul Hawley, Colonel John C. Harding, ninety-nine representatives from forty-three states and some forty others representing prepayment plans and special groups. This conference was successful. The representatives present selected six of their number to meet with the Trustees' Veterans Committee following the general conference. At this meeting ways and means of ironing out future policies were discussed. A full report of the conference was prepared and sent to each state medical society representative. Undoubtedly further report on the veteran care activities will be made by the Board of Trustees.

STUDY OF COUNTY SOCIETIES' ACTIVITIES

Special effort has been made in recent months to build up contacts with the county medical societies. Many county medical society officers receive the News Letter and attend the regional conferences. However, it has been evident that a closer contact is necessary if the Council is to report accurately on progress in the field of medical service. Many medical care programs originate and are carried out at the county level. Some examples are: cancer detection clinics, indigent medical care plans, tuberculosis case-finding programs and health councils. To evaluate these and other medical care programs, regular contact with county medical societies is necessary. The Council is carrying on a study of the activities in more than two hundred county medical societies. The purpose of this study is to create information files here in the Association offices so that the information will be available to the many county medical societies that have not, in the past, carried on activities or sponsored programs. Anyone who regularly reads the county medical society publications, more than one hundred in number, realizes that the medical profession is doing much in the support of

voluntary medical service programs that is never recognized beyond the county border. Localizing or decentralizing medical service programs is a part of the Association's policy; yet little seems to have been accumulated concerning the actual extent and progress of such decentralizing activities. The results of the Council's study should be helpful in showing what voluntary effort is accomplishing; it will aid in stimulating future effort in medical care programs where such effort has lagged, and it will enable the American Medical Association to give recognition to state and county medical societies which have successfully attacked medical care problems.

SPECIAL PROJECTS

Cash Sickness Benefits.—The Council continues to follow legislative developments in the various states and has made it a point to maintain a liaison with the Railroad Retirement Board in regard to cash sickness benefits. At the time of the June session the Council reported on the introduction of thirty-two "cash sickness" bills in the legislatures of thirteen states. Since then eleven bills have been added, making a total of some forty-three bills introduced in sixteen state legislatures. These bills generally provide for the establishment of a system of sickness benefits or "health insurance." The growth in interest in this type of legislation is shown by the fact that only ten bills were introduced in state legislatures in 1935-1936, as compared to thirty-nine in 1945 and forty-three in 1947.

Health Councils.—In October the Council released its first publication on the subject of health councils. The brochure, entitled "Medical Care Prepayment Plan Development Through a Local Health Council," was designed to stimulate interest in health councils among physicians in towns of less than 10,000 population. It stimulated far more interest than had been anticipated, and the first run of 5,000 vanished quickly. A second brochure now ready for publication is entitled "The Community Health Council." Further brochures will enter into discussions of the urban (city) and the state health councils.

Group Practice Study.—On the suggestion of the Board of Trustees the Council has appointed a Group Practice Committee to act in an advisory capacity to the Bureau of Medical Economic Research in the Group Practice Study.

Study of Cooperatives.—The study of consumer-sponsored and cooperative health service plans has identified seventy-nine such plans. Contrary to popular opinion the plans are operating in both urban and rural areas. In the forty-eight plans reporting enrollment a total of 36 per cent came from rural communities and the remaining 64 per cent came from urban areas. The total enrollment of the forty-eight plans was 674,653. The Council is continuing with the study of medical cooperatives and plans to publish a brochure on the subject this coming spring.

PREPAYMENT

The Council is continuing its active interest in the various voluntary prepayment medical care plans. Seven new plans, or programs, in as many states were completed in 1947. Thirty-eight states now have programs in operation. In several states the plans are fairly complete and should soon be in operation.

The medical society approved plans added more than 2,000,000 subscribers during the first nine months of 1947 to bring total enrollment to over 6,500,000. Enrollment in the so-called non-profit plans is at its best in Delaware, where 41.77 per cent of the population has "joined up." Other top percentages enrolled are: 26.21 in New Hampshire; 17.75 in Colorado; 17.48 in Washington, and 14.61 in Michigan.

Prepayment plans are rapidly extending into rural areas with thirty-seven reporting rural enrollment programs in operation. The plans are also broadening their coverages and are extending enrollment privileges to smaller groups and in some instances to individuals.

Recent estimates of the number of persons covered under the several types of voluntary prepayment plans are: industrial, consumer sponsored, government and university programs, 3,302,000; insurance companies (accident and health and hospital and surgical), 44,000,000; Blue Cross Hospitalization, 28,000,000, and medical society-sponsored medical care plans, 6,500,000.

Although not additive these figures total over 82,000,000. There are duplications, as some persons are covered under more than one type of prepayment program.

Current surveys are in process which are designed to produce the latest available enrollment data and make adequate allowances for duplication of coverage.

RELATIONS WITH OUTSIDE AGENCIES

In almost every medical service activity it is necessary for the medical profession to work with other groups, organizations and agencies. Recognizing this, the Council has furthered its contacts with many national agencies and organizations.

Cooperation has been developed with such groups as the American Cancer Society, the National Federation of Small Business, Inc., the United States Chamber of Commerce, the American Hospital Association, and the American Dental Association. One of the better examples of cooperation is the Joint Committee for the Chronically Ill made up of representatives of the American Medical Association, the American Public Health Association, the American Hospital Association, and the American Public Welfare Association. This Committee met recently in New York and laid careful plans for the study of chronic disease.

Respectfully submitted,

JAMES R. McVAY, Chairman.
A. W. ADSON.
WALTER B. MARTIN.
THOMAS A. MCGOLDRICK.
J. D. HAMER.
ELMER HESS.
H. H. SHOULDER.
EDWARD L. BORTZ.
E. J. MCCORMICK.
GEORGE F. LULL.

The House recessed at 12:50 p.m., to reconvene at 2:30 p.m.

Monday Afternoon

The House reconvened at 2:45 p.m., with the Speaker, Dr. R. W. Fouts, presiding.

NEW BUSINESS

Resolution Requesting Amendment to By-Laws to Increase Fellowship Dues

Dr. Allen H. Bunce, Georgia, reintroduced the resolution dealing with an amendment to the By-Laws whereby the Fellowship dues would be increased, and the Speaker referred the resolution to the Reference Committee on Amendments to the Constitution and By-Laws.

Resolution on Intern and Resident Training

Dr. Hilton S. Reed, New Jersey, introduced the following resolution, which was referred to the Reference Committee on Medical Education:

WHEREAS, Medical students are by virtue of training requirement and organizational setup required to blueprint their program of training in their late junior or early senior year; and

WHEREAS, It is becoming increasingly difficult for American Medical Association approved hospitals other than those associated with teaching institutions to secure interns and residents; therefore be it

Resolved, That a committee of this House, including two general practitioners, be appointed to study (a) the potentialities of requiring, in the interest of promoting general practice, a year of rotating internship before permitting a candidate to elect specialty training, and (b) the supply and techniques of distribution of interns and residents and report to this House at the June session.

Resolution on Proper Integration of Training of Nurses

Dr. J. Morrison Hutcheson, for the Medical Society of Virginia, presented the following resolution, which was referred to the Reference Committee on Medical Service:

WHEREAS, Competent nursing is an integral part of medical practice and a proper concern of physicians and medical organizations; and

WHEREAS, The increasing shortage of nurses during recent years has now reached alarming proportions and seriously handicaps medical care; and

WHEREAS, At several sessions of the House of Delegates of the American Medical Association committees have been appointed to look into the manner, and at the last session in June 1947 a committee of five to be appointed by the president was authorized to study all aspects of the question; and

WHEREAS, The current system of training nurses is a principal cause of this shortage and no relief may be expected until it is revised; and

WHEREAS, The curriculum which has been evolved during the past few decades and which is in operation at present has failed to produce better nurses, as more and more time has been devoted to the study of supposedly ancillary subjects with the consequent neglect of training in the practical art of caring for the sick, with the result that the present day graduate is not so well prepared to meet the patient's needs as were her sisters of a generation ago; and

WHEREAS, The present trend toward the formation of a new group of practical nurses is a significant development illustrating the need and demand for more effective nursing service; therefore be it

Resolved, By the house of delegates of the Medical Society of Virginia in session on Oct. 14, 1947, at Roanoke, Virginia, that a proper integration of the training of the two groups of nurses should be effected in such a way as to best serve the purpose of good medicine, the welfare of the patient, the continued development of the nursing profession, and provide an adequate number of nurses trained in the art and practice of bedside nursing and that this resolution be presented to the House of Delegates of the American Medical Association, and copies sent to the Special Committee on Nursing of the American Medical Association, the Nurses Association of Virginia, and the National Nurses Association.

Resolutions on Distribution of Interns

Dr. Edgar P. McNamee, Ohio, presented the following resolutions, which were referred to the Reference Committee on Medical Education:

WHEREAS, The number of positions for intern medical training in approved hospitals exceeds by a large number the available interns; and

WHEREAS, It is becoming increasingly more difficult each year for approved hospitals and those hospitals desiring approval to secure interns from class A schools; and

WHEREAS, Approved hospitals that provide excellent opportunities for interns and residents to gain practical experience in a considerable amount under qualified physicians and surgeons are finding it exceedingly difficult to compete with the medical teaching institutions and large medical centers; and

WHEREAS, An agreement for internship placement was formulated by the Association of American Medical Colleges and agreed to by the Council on Medical Education and Hospitals of the American Medical Association, and the American, Protestant, and Catholic hospital associations; therefore be it

Resolved, That the House of Delegates of the American Medical Association be requested to take such action as will result in the rigid adherence by all hospitals to the plan for internship placement; and be it further

Resolved, That the House of Delegates of the American Medical Association instruct the Council on Medical Education and Hospitals to study this problem of unequal distribution of interns and formulate a plan in cooperation with the Association of American Medical Colleges, the American Hospital Association, the Catholic Hospital Association and the Protestant Hospital Association limiting the number of interns per hospital or institution on the basis of bed capacity further to insure an equitable distribution of interns.

Resolution on Fixing Date of Interim Session

Dr. Karl S. J. Hohlen, Nebraska, presented the following resolution, which was referred to the Reference Committee on Rules and Order of Business:

WHEREAS, There is a resolution now pending before the House that the delegates to the American Medical Association take office January 1 next following their election; and

WHEREAS, Unless a definite date be fixed for the interim session of the House of Delegates, complications will arise affecting the number of sessions which a delegate may attend during his term of office; therefore be it

Resolved, That the interim session of the House of Delegates of the American Medical Association be held in the month of December, the exact date to be fixed by the Board of Trustees.

Resolution on Endorsement of National Multiple Sclerosis Society

Dr. Hans H. F. Reese, Section on Nervous and Mental Diseases, presented the following resolution, which was referred to the Reference Committee on Medical Education:

WHEREAS, Multiple sclerosis is a condition of increasing concern to the medical profession; and

WHEREAS, There are many involved problems related to its etiologies and treatment schedules; and

WHEREAS, A new organization with a qualified medical advisory board has been formed to devote itself particularly to the solution of such problems; therefore be it

Resolved, That the American Medical Association endorse officially the attempt to educate the public concerning the disease and to undertake investigations leading to a solution of its problems in qualified hospital and medical centers.

Resolutions on Disapproval of Principles of Grants-in-Aid to All States Regardless of Established Actual Need

Dr. T. K. Lewis, New Jersey, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, Title VII of Senate Bill No. 545, now pending in the 80th Congress, implicitly premises the assumption that all states, in varying degree, need financial assistance from the federal government to carry out the purposes of this Title; and

WHEREAS, The platform of the American Medical Association, adopted by the House of Delegates of the American Medical Association, June 13, 1944, advocates (Section D) "The allotment of such funds as the Congress may make available to any state in actual need for the prevention of disease, the promotion of health and the care of the sick on proof of such need"; and

WHEREAS, The philosophy of grants-in-aid to the states without demonstrated actual need, as contemplated in Title VII of S. 545, contravenes the basic principles of the platform of the American Medical Association as to "the allotment of such funds"; therefore be it

Resolved, That the House of Delegates of the American Medical Association, while in accord with the objectives of Title VII of S. 545, "Improved medical care services and hospital care for families and individuals with low income," registers its disapproval of the principles of grants-in-aid to all states regardless of established actual need, expressed in Title VII, in the conviction that the majority of states do not need federal financial assistance to carry out the purposes of this Title; and be it further

Resolved, That copies of this resolution be forwarded to the sponsors of S. 545, to the other members of the Senate and to the members of the House of Representatives.

Resolutions on Approval of Training of Residents and Interns

Dr. James P. Kerby, Utah, presented the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The practice of radiology, pathology and anesthesiology is recognized by the American Medical Association as the practice of medicine; and

WHEREAS, Leading hospital organizations of the United States have recognized this fact; and

WHEREAS, There is a tendency on the part of certain hospital administrators to utilize the profits resulting from the operation of these departments in their institutions; and

WHEREAS, This constitutes exploitation of professional medical services; and

WHEREAS, This is contrary to medical ethics; therefore be it

Resolved, That it is the sense of the Council that this practice should be condemned; and be it further

Resolved, That the Council of the Utah State Medical Association urge the House of Delegates of the American Medical Association to instruct the Board of Trustees of the American Medical Association to direct the Council on Medical Education and Hospitals to refuse approval for training of residents and interns of any hospital exploiting professional medical services.

Resolutions on Limitation of Tenure of Office of Delegates

Dr. William H. Halley, Colorado, presented the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

WHEREAS, There is increasing concern in a number of constituent associations because of inadequate participation in the affairs of the American Medical Association by younger members of the profession; and

WHEREAS, Many constituent associations are endeavoring to stimulate the active interest of younger members to meet the challenge of rapidly changing socio-economic factors; and

WHEREAS, President Bortz has recognized the wisdom of indoctrinating younger members in the problems of organized medicine; and

WHEREAS, It is an established principle that a legislative body is the final judge of the qualifications of its members; now, therefore, be it

Resolved, That to encourage the participation of younger physicians in the policy-making bodies of the American Medical Association, the principle of limitation of tenure of office already applicable to many offices of the Association be extended to include the members of the House of Delegates of the American Medical Association; and be it further

Resolved, That the Committee to Study the Revision of the Constitution and By-Laws be instructed to prepare suitable amendments to make this policy effective.

Resolutions on Geographic Selection of Trustees of American Medical Association

Dr. William E. Halley, Colorado, presented the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The complex problems of the practice of medicine are complicated by geographical differences; and

WHEREAS, Physicians are more conversant with conditions in their respective regions than are those resident in other areas; now, therefore, be it

Resolved, That in order to insure geographic representation on the Board of Trustees for consideration of problems arising in all districts of the United States, each member of the Board of Trustees of the American Medical Association shall be selected from a different geographic area; and be it further

Resolved, That the Committee to Study Revision of the Constitution and By-Laws be directed to prepare suitable amendments to make this policy effective.

Resolutions on Regulation of the Practice of Pathology by Registered and Approved Hospitals

Dr. A. S. Giordano, Indiana, presented the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The House of Delegates has adopted the Vest resolution designed to curb the encroachments of hospitals and institutions on the practice of medicine; and

WHEREAS, The hospitals frequently consider the pathology department as a source of income for the hospital; and

WHEREAS, The practice of pathology has been repeatedly defined by the House of Delegates as the practice of medicine; and

WHEREAS, The American Medical Association's "essentials of a registered hospital" specifically state that the radiology department should not be operated for a profit; therefore be it

Resolved, That the American Medical Association's "essentials of a registered hospital" be amended to include the statement that the pathology department should not be operated for a profit; and be it further

Resolved, That this same principle shall be included in the interpretation of the essentials for an approved internship and the essentials for an approved residency.

Resolution on Propaganda Distributed to the Armed Forces

Dr. Herbert H. Bauckus, New York, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, I hold in my hand a copy of "Is Your Health the Nation's Business?" issued by the War Department for use of personnel of the Army, Navy, Marine Corps and Coast Guard, which while it purports to present impartially both sides of the arguments for and against government-controlled sickness insurance for use in round table discussions by personnel of the armed forces, actually quotes at length without their true identity and propaganda purposes being revealed the platform of the American Public Health Association and health conference report; and

WHEREAS, The arguments against government control are presented weakly and inconclusively, containing the usual disclaimer that "It is not to be inferred that the War Department endorses any one of the particular views presented" and "distribution of this pamphlet is not to be construed as an endorsement by the Navy Department of the statements contained therein"; and

WHEREAS, The effect would be to regard the pamphlet as the official position of the government; therefore be it

Resolved, That the House of Delegates of the American Medical Association call to the attention of the Board of Trustees the pamphlet "Is Your Health the Nation's Business?" prepared for the use of the United States Armed Forces by the American Historical Association, with the request that it be referred to the appropriate Council for action, such action to include the lodging with the proper government official of a protest against the issuance of such propaganda to members of the armed forces.

Resolutions on Red Cross Blood Program

Dr. Robertson Ward, California, presented the following resolutions, which were referred to the Reference Committee on Medical Service:

WHEREAS, The procurement and distribution of human blood in time of peace is a matter for joint cooperation between the medical profession and the appropriate private or commercial laboratories; and

WHEREAS, Many medical associations have already set up and are successfully conducting nonprofit blood banks; therefore be it

Resolved, That this House of Delegates does not regard it as a proper function of the American Red Cross to engage in a blood bank program in the United States in time of peace; and be it further

Resolved, That this resolution rescinds the former "Approval in Principle" granted to the so called Red Cross Blood Program by this House.

Resolution on Diagnosis of Tuberculosis

Dr. Burt R. Shurly, Se on on Laryngology, Otolaryngology and Rhinology, presented the following resolution, which was referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, Case finding with x-rays of the chest has produced great results in the early diagnosis of pulmonary tuberculosis; and

WHEREAS, The more extensive use of these methods will do much toward the elimination of contagion and the prevention of this disease; therefore be it

Resolved, That the American Medical Association be requested to give extra efforts in the publication of these methods and that these methods be afforded to all school children and teachers throughout this country.

Resolutions on Examination of Immigrants

Dr. John W. Cline, California, presented the following resolutions, which were referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, As a result of world conditions, disease, including tuberculosis and other communicable diseases, is widespread in many portions of the world; and

WHEREAS, Persons living in these places are seeking admission to this country as immigrants; and

WHEREAS, Admission of persons having such diseases constitutes a public health hazard, most particularly so in coastal states where the U. S. Immigration Service maintains ports of entry; therefore be it

Resolved, That the American Medical Association call this situation to the attention of the Congress, the United States Public Health Service, and the proper immigration authorities; and be it further

Resolved, That these agencies of government be requested to require adequate and reliable physical examination, including x-ray examination of the chest, prior to and as a condition of admission to this country; and be it further

Resolved, That if such examination cannot be secured prior to leaving the country of origin the immigrant seeking admission be so examined at the proposed port of entry.

Tribute to Dr. Archer C. Sudan

Dr. William H. Halley, Colorado, presented the following statement concerning the election of Dr. Archer C. Sudan, Kremmling, Colo., to receive the General Practitioner's Award: *Mr. Speaker and Members of the House:*

This is a proud hour in the history of the Colorado State Medical Society. On behalf of my colleagues, of the whole Society, I take this opportunity to thank you for the great honor you have paid to Dr. Sudan and to the general practice of medicine in the wide open spaces of the Rocky Mountain west.

Our spaces are wide, and as those of you who have seen the Rocky Mountains know, our miles are sometimes vertical as well as horizontal. They are big miles. Doctor Sudan is a big man, as all of you will know if you can meet him Wednesday evening.

It does not diminish our appreciation one whit to say that we in the Rocky Mountain region believe that you chose well when you chose Dr. Sudan for the General Practitioner's Award. We thank you, beyond our ability to put it into words.

Invitation from New York

Dr. James R. Reuling, New York, presented the following invitation, which was referred to the Board of Trustees for its information:

1949 INTERIM SESSION

The Council of the Medical Society of the State of New York has received and approved a letter received under date of December 30, 1947, which reads as follows:

W. P. Anderton, M.D., Secretary
Medical Society of the State of New York
292 Madison Avenue
New York City

Dear Doctor Anderton:

The Comitia Minora of the Medical Society of the County of New York beg to extend a warm and cordial invitation to the American Medical Association to hold the Interim Meeting of the House of Delegates of the American Medical Association in January in 1949 in the City of New York.

We should be deeply grateful to be hosts to the House of Delegates and would very much appreciate the courtesy of your extending this official invitation to the House of Delegates.

On behalf of the Comitia Minora, I beg to remain

Yours very cordially.
(Signed) B. Wallace Hamilton, M.D.,
Secretary.

From the New York Convention and Visitors' Bureau and from the Mayor of New York City also are attached invitations to this House of Delegates to hold its Interim Session, 1949, in New York City, and assurance is given that satisfactory facilities are available.

New York City and its environs contain the largest concentration of general practitioners in this country.

The delegation from New York take pleasure in presenting this invitation.

Motion on Meetings of Reference Committees

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. E. S. Hamilton, Illinois, and carried, the reference committees were requested to meet immediately after the House recessed for the day.

Request for Meeting of Council on Scientific Assembly with Committee to Study Revision of Constitution and By-Laws

Dr. F. F. Borzell, vice chairman, requested the Council on Scientific Assembly to meet with the Committee to Study Revision of the Constitution and By-Laws, of which committee Dr. Borzell is chairman.

Motion on Adjournment

It was moved by Dr. Mather Pfeiffenberger, Illinois, seconded by Dr. B. H. Minchew, Georgia, and carried after discussion, that when the House recesses for the day, it recess until tomorrow morning at 10 a.m.

Disposition of Nominations for General Practitioner's Award

Dr. Walter F. Donaldson, Pennsylvania, requested that letters be sent those who sent in nominations for the General Practitioner's Award thanking them and informing them concerning who was awarded the medal. The request was seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried after discussion by Dr. George F. Lull, Secretary, the Speaker and Dr. Donaldson. The Secretary, Dr. George F. Lull, informed the House that if any nominee for the award this year is to be given consideration at a future time a new recommendation should be made.

Invitation to Meet in St. Louis

Dr. Robert E. Schluter, Missouri, in behalf of the Missouri State Medical Association, the St. Louis Medical Society and the whole profession of the State of Missouri, extended an invitation to the House of Delegates to hold its next Interim Session in St. Louis. The Speaker requested that the invitation be filed with the Board of Trustees for its guidance.

After Dr. F. F. Borzell, Vice Speaker, reread the list of members of reference committees, the House recessed at 3:40 p.m. to meet at 10 a.m. on Tuesday, Jan. 6, 1948.

(To be continued)

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 9-10. Dr. Donald G. Anderson, 535 North Dearborn St., Chicago 10, Secretary.

National Conference on Rural Health, Chicago, Palmer House, Feb. 6-7. Dr. F. S. Crockett, 535 N. Dearborn St., Chicago 10, Chairman.

American Academy of Orthopaedic Surgeons, Chicago, Palmer House, Jan. 24-29. Dr. Harold B. Boyd, 869 Madison Ave., Memphis, Tenn., Secretary.

American Society for Surgery of the Hand, Chicago, Jan. 23-24. Dr. Joseph H. Boyes, 1401 S. Hope St., Los Angeles 15, Secretary.

Southeastern Allergy Association, Richmond, Va., Jefferson Hotel, Jan. 17-18. Dr. Katharine B. MacInnis, 1515 Bull St., Columbia 49. S. C., Secretary.

Official Notes

ELECTRICAL TRANSCRIPTIONS

"Music With Your Meals"

Available Jan. 15, 1948 from the Bureau of Health Education will be a new series of electrical transcriptions, entitled "Music With Your Meals." The topics and speakers of the thirteen quarter-hour programs are as follows:

Nutrition and Health.....	Dr. John B. Youmans
Foods We Eat	Dr. George R. Cowgill
Shopping for Food	Dr. Russell M. Wilder
The Champion Breakfast	Dr. Harold R. Sandstead
The Luncheon Problem	Dr. W. H. Sebrell Jr.
The School Lunch	Dr. Dean F. Smiley
The Evening Meal	Dr. Richmond K. Anderson
Eating Between Meals	Dr. Philip C. Jeans
Psychology of Eating.....	Dr. Henry Poncher
Special Diets	Mrs. Dorothea Turner
Food Allergies	Dr. Samuel M. Feinberg
Food Fads and Fallacies	Dr. James S. McLester
Food Poisoning	Dr. Walton Van Winkle

These interview-type scripts are by Harriet Hester; the music is by Albert Salvi, concert harpist; the interviewer is Elizabeth Hart; the recording is RCA high fidelity orthocoustic. Scripts, posters and press releases accompany the recordings. Local use is conditioned on approval by the county medical society. Transcriptions are available in complete series only, on loan free of all charge except return transportation. Local groups are expected to take appropriate responsibility for successful broadcasting and for return of platters.

Washington Letter

(From a Special Correspondent)

Jan. 15, 1948.

Hawley Committee Studies Improvement of Service Medical and Hospital Facilities

Secretary of Defense Forrestal has asked the special committee headed by Dr. Paul R. Hawley, former Veterans Administration medical director, to submit ideas on how to devise the most efficient medical service for the unified armed forces. He requested comment on the wisdom of establishing a single hospital service. Committee members are the medical chiefs of the Army, Navy and Air Force. Mr. Forrestal said in a memorandum that "What I wish is a thorough, objective and impartial study of the medical services of the armed forces with a view to obtaining, at the earliest possible date, the maximum degree of coordination, efficiency and economy in the operation of these services. . . . The matter of training of medical corps personnel—whether or not they should receive the same training and then be assigned to the services and just how the various hospitals and medical units should be manned—will be taken up by the committee. In short, the Hawley committee has been instructed to make an exhaustive study of the whole medical field and come up with some definite recommendations." Mr. Forrestal suggested specific study of various subjects, including the question of whether certain types of medical service required by the armed forces could be performed more efficiently and economically by utilizing civilian hospital facilities.

Government Sells One Hundred and Eight Hospitals and Nurses' Homes

The Federal Works Agency announced that it had sold one hundred and eight hospitals and nurses' homes, along with four hundred and ninety-three schools, waterworks and other community facilities, at less than a third of the original cost. Many were built during the war.

GOVERNMENT SERVICES

ARMY

TRAINING IN NEUROPSYCHIATRY

The Surgeon General has announced details of the policy relating to advanced professional training in neuropsychiatry, a part of the Army's graduate medical training program. This program will be offered in three Army general hospitals accredited for such training by the Council on Medical Education and Hospitals of the American Medical Association.

The announced policy requires five consecutive years of professional training, providing the prerequisites for admission to examination by the American Board of Psychiatry and Neurology. The officer resident will be retained in this training program unless he is dropped by direction of the Surgeon General following recommendations of a Hospital Education Committee to the effect that the officer lacks professional aptitude.

The five years of training will include three years of formal residency and two years of on the job training that meets standards of the American Board of Psychiatry and Neurology for one or the other of these two specialties. It is contemplated that the officer resident will start in formal training and that the two years of on the job training may be given following the first, second or third year of formal training. However, as far as possible the five individual training years will be consecutive.

Residencies are open to all graduates of accredited medical schools, including the Army Specialized Training Program, who are eligible and have applied for commissions in the Regular Army. These Army of the United States officers are eligible for such commissions after six months of service and receive a \$100 per month increase in pay when accepted.

Although a specified number of years of service is not required after completion of a residency board certification, it is expected that the applicants intend in good faith to make a career of the Regular Army.

REENLISTMENTS FOR GI'S CROWDED OUT OF COLLEGES

The Army and Air Force, recognizing that veterans using their GI Bill of Rights benefits have filled many of the housing accommodations and classes at most of the nation's colleges and universities, have made it possible for men serving short term enlistments to continue in uniform on a standby basis until the institution they wish to attend under the GI Bill has room for them. Under the new plan those in the Army or Air Force who

have unused educational benefits under the GI Bill of Rights may extend their enlistments to three, four or five years with the promise that they will be discharged at any time subsequent to completion of their original term of enlistment in order to use their educational benefits. In every case discharge will be accomplished a full month before the beginning of the school term.

SCIENTIST ADDED TO ASSISTANT SECRETARY'S STAFF

A scientific assistant to the Assistant Secretary of the Army is to be appointed as soon as practicable, the Secretary of the Army announced Dec. 17, 1947. The scientific section will be established in the Assistant Secretary's office to assure for the Army the best possible guidance in research activities and their correlation with those of other scientific staffs of governmental, educational and private institutions throughout the country. The Secretary of the Army recently announced the reconstituting of the Research and Development Division of the General Staff.

ARMY AWARDS AND COMMENDATIONS

Colonel Lee D. Cady

The Legion of Merit has been awarded to Col. Lee D. Cady, M. C., now with the Veterans Administration in Dallas, Texas. The citation read as follows: He rendered exceptionally meritorious service in North Africa, Italy and France from January 1943 to May 1945, as commanding officer, 21st General Hospital. He skilfully directed a threefold expansion of the hospital and perfected its flexibility and ability to handle successfully increased emergency needs for close medical support of tactical operations. He developed an adapted engineer-utility unit capable of meeting urgent construction and operating needs of an isolated general hospital. He also initiated or improved and developed for general application valuable professional and administrative techniques. Under his vigorous and energetic leadership, an exceptional standard of medical treatment was maintained despite a series of long distance moves required by a succession of campaigns. Dr. Cady graduated from Washington University School of Medicine, St. Louis, in 1922 and entered military service in January 1942.

VETERANS ADMINISTRATION

SHORTAGE OF MEDICAL LIBRARIANS

Mr. Francis R. St. John, director of library service of the Veterans Administration, states that there is an acute shortage of medical librarians. They are needed to assist in the medical program of the Veterans Administration. The specialized techniques in medical reference work, bibliography and medical research are especially needed to make medical literature available to residents and interns in the Veterans Administration medical training program. In THE JOURNAL, Oct. 11, 1947, page 358, reference should have been made to the training of hospital librarians rather than to the training of medical record librarians. There are no medical record librarians in the library service program of the Veterans Administration.

CONTRACTS FOR HOSPITALS

Scaled bids are being accepted for the construction of a hundred and fifty bed addition to the Veterans Administration tuberculosis hospital in Portland, Ore. Sets of specifications are available to plumbing, heating and electrical firms for use in preparing sub-bids for general contractors. Although no

deposit is necessary, the specifications must be returned in ten days after the bids are opened publicly on February 24. Bids may be submitted to the central office of the Veterans Administration, Washington, D. C., until that date.

The contract for construction of the veterans' two hundred bed general hospital at Poplar Bluff, Mo., has been awarded to the low bidder for \$5,082,500.

NEW CHIEF OF CLINICAL PSYCHOLOGY

Harold M. Hildreth, Ph.D., has been appointed chief of clinical psychology of the Veterans Administration to succeed J. G. Miller, who has resigned to accept the chairmanship of the department of psychology at the University of Chicago. Dr. Hildreth received his Ph.D. degree from Syracuse University and his A.B. from the University of Nebraska. Formerly he was psychologist at the Syracuse Psychopathic Hospital and senior psychologist for the U. S. Navy; he served at the training station at Sampson, N. Y., and at the naval hospitals at Seattle and Mare Island. He also assisted in the program of the National Research Council for developing tests to select suitable persons for training as pilots in the armed forces.

HOME TOWN PHARMACY PLAN

The Veterans Administration has announced the resignation of Professor W. Paul Briggs, chief of the pharmacy division, who during his twenty-one months of service, among other things, established a home town pharmacy program in the Veterans Administration with the cooperation of state pharmaceutical associations to provide drugs at local pharmacies to veterans with service-connected disabilities undergoing outpatient treatment. Professor Briggs also developed a procedure for the selection of drugs used in veterans' hospitals and homes by creating standing committees on therapeutic agents in each field station. He was for many years professor of pharmacy and dean of the school of pharmacy at George Washington University, Washington, D. C., and was treasurer of the U. S. Pharmacopeia.

WOMEN VETERAN PATIENTS

There were 2,035 hospitalized women veterans under the care of the Veterans Administration as of October 1947, an increase of 905 in the previous fifteen months. In addition, another 238 women veterans were being cared for in veterans' domiciliary homes, bringing the total number of women under Veterans Administration care at that time to 2,273. Of the 2,035 in hospitals, 1,152 were general medical and surgical patients; 246 had tuberculosis; 502 were psychotics and 135 had other neuropsychiatric disorders.

Disability compensation or pension as a result of war service was being given to 13,652 women veterans of World War II as of last June 30, and to 4,564 women veterans of World War I.

PUBLIC HEALTH SERVICE

AVAILABILITY OF MALARIA TO TREAT NEUROSYPHILIS

The U. S. Public Health Service since 1931 has distributed malaria inoculums to qualified physicians and institutions for the treatment of neurosyphilis. The material is sent regularly on the Tuesday following the date of the request, and shipment is usually made by air express collect. Those desiring malaria inoculums should address requests to Dr. Martin D. Young, Post Office Box 1344, Columbia, S. C. A vacuum bottle of at least 1 pint capacity should be sent. Information as to the species of malaria desired should accompany the request, as well as the following information: number of patients to be inoculated; race of patients; previous history of malaria, including species. Ordinarily, *Plasmodium malariae* (quartan malaria) should be used for white patients who have had a previous infection of *Plasmodium vivax* (tertian malaria) and for all Negro patients. *P. vivax* is ordinarily used for white patients without a history of malaria.

AWARDS FOR CANCER TEACHING AND CONTROL

The National Advisory Cancer Council of the U. S. Public Health Service awarded \$1,500,000 during December to colleges, research laboratories and public health institutions throughout the country. Of this sum, \$593,130 was awarded to twenty-six medical schools for the improvement of cancer teaching and nearly \$750,000 in forty-six grants was awarded for clinical and basic bacteriologic research. For the first time grants were given to scientists working outside the United States. Dr. A. Lacassagne of the Pasteur Institute in Paris, France, being awarded \$13,380 and Dr. L. Doljanski of the Hebrew University in Palestine \$10,000. Grants made for cancer control projects totaled \$132,645; they ranged from \$7,670 given to the University of Tennessee for a cancer tissue diagnosis service and tumor registry to \$30,000 to Memorial Hospital, New York, for cancer pathology and medical training. The Memorial Hospital also received more than \$100,000 for a total of five research projects, constituting the largest research grant given a single institution by the National Advisory Cancer Council.

MENTAL HYGIENE CLINIC FOR VETERANS

A newly organized mental hygiene clinic has been opened in Hartford, Conn., for full time operation by the Veterans Administration. The clinic is headed by Dr. Isadore Schnap, formerly chief of the neuropsychiatric service at the veterans' hospital in Newington, Conn. Facilities are available for the outpatient treatment of those with service-connected neuropsychiatric conditions.

DR. HAWLEY DECORATED

The Norwegian government on Dec. 27, 1947 decorated Dr. Paul R. Hawley, at that time chief medical director of the Veterans Administration, with the Order of Saint Olav, commander grade, for his medical work with Norwegian forces through the government in exile in London. During the war Dr. Hawley was a major general serving as chief medical officer of the U. S. Army in the European theater of operations.

PERSONAL

Dr. William G. Lewis has been assigned as clinical director and chief of professional services at the veterans' hospital, Walla Walla, Wash. Previous to the war Dr. Lewis was physician in charge of the U. S. Indian Hospital in Santa Fe, N. Mex., and during the war he served with the 30th Evacuation Hospital in the Philippine Islands.

NEW ASSISTANT SURGEON GENERAL

The Surgeon General has announced the appointment of Mark Dexter Hollis as assistant surgeon general and chief of the Sanitary Engineering Division of the U. S. Public Health Service effective January 1, replacing John K. Hoskins, who retired after thirty-four years of service. Mr. Hollis comes to the headquarters office from the Communicable Disease Center, Atlanta, Ga., where he was officer in charge. He directed a comprehensive program for the control of malaria and typhus among military personnel in the United States. During his ten years with the service Mr. Hollis has carried on other important programs in sanitary engineering and preventive medicine.

MORE GRANTS FOR RESEARCH IN MENTAL HEALTH

The Federal Security Agency, Washington, D. C., announces the award of six more grants for research in mental health under the National Mental Health Act. The grants were recommended by the National Advisory Mental Health Council and were approved by the Surgeon General of the U. S. Public Health Service. Twenty-five grants in this field had been awarded previously. The six recent grants were awarded to the following institutions:

- University of California, Berkeley, Calif.
Directors of Project: Dr. Karl M. Bowman, professor of psychiatry, and Dr. Jurgen Ruesch, research psychiatrist, the Langley Porter Clinic.
- Columbia University, College of Physicians and Surgeons, New York.
Director of Project: Dr. Abner Wolf, associate professor of neuropathology.
- Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine.
Director of Project: J. P. Scott, D.V.M., chairman, Division of Behavior Studies.
- Mu Iota Sigma Fraternity, Illinois School for the Deaf, Jacksonville, Ill.
Director of Project: M. Arline Albright, associate professor of education and psychometrist, Milwaukee.
- Wayne University School of Public Affairs and Social Work, Detroit.
Directors of Project: Fritz Redl, professor of social work, and Ronald Lippitt, director of research (Research Center for Group Dynamics, Massachusetts Institute of Technology, Cambridge, Mass.)
- Wesleyan University, Middletown, Conn.
Director of Project: David C. McClelland, assistant professor, Department of Psychology.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest; such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Plague Infection in Wood Rats.—The California Department of Public Health reports that tissue from 4 wood rats collected near the Fitzhugh Ranger Station in Modoc County were proved positive for bubonic plague in the laboratory of the University of California Hooper Foundation. A human case of plague occurred in this locality early in the summer.

Dr. Nelson Appointed Assistant Dean.—Dr. Norman B. Nelson, associate professor of public health and chairman of the department, University of California at Los Angeles, has been appointed assistant dean of the School of Medicine. He will assist Dr. Stafford L. Warren in picking a staff and planning the buildings in the new medical school. Dr. Nelson, a graduate of the University of California at Los Angeles, was formerly medical director of the Los Angeles City Health Department.

Outbreak of Q Fever.—The state department of public health on Dec. 13, 1947 reported an outbreak of Q fever in Southern California, with 116 cases discovered since May. It is the third major outbreak in the United States. Previous outbreaks of Q fever occurred in the stockyards area of Chicago and Amarillo, Texas, last year. The U. S. Public Health Service and the Army Medical School are working with state and local authorities to learn if cattle are reservoirs for the disease and how it is transmitted. A laboratory for the study of Q fever was established in the Los Angeles area early this year (THE JOURNAL, Nov. 29, 1947, p. 859).

COLORADO

Research in Trichinosis.—A research grant of \$4,000 has been made to Dr. James B. McNaught, professor of pathology at the University of Colorado Medical Center, Denver, by the Lilly Research Laboratories of Eli Lilly & Company, Indianapolis, for experimental studies of therapeutic agents in trichinosis.

Dr. Sabin to Head Denver's Health Service.—Dr. Lawrence R. Sabin, Denver, became the city's manager of health and charities January 1, succeeding Dr. Solomon S. Kauvar, who resigned to resume private practice. Dr. Sabin, now president of the Western branch of the American Public Health Association, has been head of the state subcommittee on health. She had retired a few years ago from the Rockefeller Institute of Medical Research, New York.

Wading Tank for Poliomyelitis Patients.—Under a grant from the National Foundation for Infantile Paralysis, the University of Colorado Medical Center, Denver, has received a special treatment wading tank for poliomyelitis patients, which is said to be the second of its kind to be made in the United States. The first was installed at the Georgia Warm Springs Foundation, and the third is to be prepared for the Mayo Clinic, Rochester, Minn. The tank is being installed in the department of physical medicine and rehabilitation.

ILLINOIS

State Program to Control Syphilis.—The state department of public health has made contracts with twenty-three hospitals throughout the state to provide facilities for the rapid treatment of syphilis. Any person suffering from infectious syphilis who is unable to pay for treatment may be sent to these hospitals at state expense for the full course of rapid treatment. The department also maintains thirty-one clinics throughout the state, where any one may go for a diagnosis of venereal disease. Trained workers are employed to follow up the contacts of patients with venereal disease, and laboratory service is available to aid physicians in diagnosing cases.

Chicago

Guest Speakers on January 21.—At the January 21 meeting of the Chicago Medical Society in the John B. Murphy Memorial Auditorium Dr. Clayton T. Beecham, Philadelphia, will speak on "Treatment of Postpartum Hemorrhage" and Dr. Joseph Trueta, Nuffield Institute for Medical Research, Oxford, England, on "Renal Circulation and Its Clinical Importance." A dinner in honor of the guest speakers will be held at the Drake Hotel at 5:30 p. m. Call the Chicago Medical Society for reservations.

Appointments at the Hektoen Institute.—At the annual meeting of the board of trustees of the Hektoen Institute for Medical Research, held on Dec. 22, 1947 at the University Club, the following appointments were made: Dr. John B. O'Donoghue, professor of surgery, Loyola University School of Medicine; Dr. Frederick H. Falls, chairman of the department of obstetrics and gynecology, University of Illinois College of Medicine, and Mr. Irv Kupcinet, as members of the board. Drs. Morris T. Friedell, Louis P. River, Oak Park, and Donald D. Kozoll, Evanston, were appointed as research associates, and Dr. William S. Hoffman as director of biochemistry.

Dr. Armstrong Appointed to Presbyterian Hospital Staff.—Dr. S. Howard Armstrong Jr., Boston, has been appointed full time chairman of the department of medicine at Presbyterian Hospital, and will have charge of the department's educational and research work. He succeeds Dr. Ralph C. Brown as head of the department of medicine, heretofore an honorary position carrying no remuneration. Dr. Brown, having reached the retirement age, resigned June 1, 1947 and is now on the consulting attending staff. The hospital is enlarging its research activities by setting up a laboratory of medicine, which will be equipped early this year under Dr. Armstrong's direction, in buildings formerly occupied by Rush Medical College. Laboratories of pathology and biochemistry were established previously. Dr. Armstrong is a graduate of Harvard University Medical School, Boston, 1937, and has devoted the last seven years to graduate study of internal medicine at Harvard and the Massachusetts Institute of Technology.

IOWA

Society News.—Dr. Sterling Bunnell, San Francisco, will address the Linn County Medical Society at its meeting at the Hotel Montrose, Cedar Rapids, January 22 at 6 p. m. on "The Reconstruction of the Hand."

MICHIGAN

Dr. McClure Honored.—Dr. Roy D. McClure, surgeon in chief of Henry Ford Hospital, Detroit, was honored at a testimonial dinner given by his surgical residents and associates, past and present, at the Detroit Club Nov. 22, 1947. Over fifty men, most of whom had received the major part of their surgical training under Dr. McClure, were in attendance. Among the speakers were Dr. Samuel F. Marshall, Boston; Dr. Henry N. Harkins, Seattle; Mr. Charles F. Kettering, Detroit, and Mr. Edgar A. Guest, Detroit. A presentation speech was made by Dr. William A. Altemeier, Cincinnati. The gift was a television set.

Dr. Seevers Made Associate Dean.—Dr. Maurice H. Seevers, chairman, department of pharmacology, University of Michigan Medical School, Ann Arbor, has been appointed associate dean of the medical school. Dr. Seevers will continue to serve as head of his department. He was graduated from Rush Medical College in 1932 and served as instructor in pharmacology and physiology at Loyola University School of Medicine, Chicago, from 1928 to 1930, when he became assistant professor of pharmacology at the University of Wisconsin. He was promoted to associate professor in 1934 and remained on the Wisconsin faculty until 1942, when he went to Ann Arbor.

NEW JERSEY

Annual Conference on Protein Metabolism.—The fourth annual Conference on Protein Metabolism, sponsored by the Bureau of Biological Research, Rutgers University, will be held in New Brunswick February 6-7. The discussions will pertain to intermediary protein metabolism, accessory substances, endocrine relationships and therapeutic aspects. The conference is open to any one whose registration is received by January 24. Blanks may be obtained from Professor William H. Cole, Rutgers University.

MISSOURI

Rehabilitation Institute a Community Project.—The Rehabilitation Institute, 2700 McGee Street, Kansas City, is now operating as a community project sponsored by the Jackson County Medical Society, the county society for crippled children, the county chapter of the National Foundation for Infantile Paralysis, the Goodwill Industries, and three social service organizations. The institute makes available to the members of the medical profession specialized services in the three departments of physical therapy, occupational therapy and a sheltered work unit. Patients are accepted only on recommendation of their physicians, who prescribe treatment, receive periodic reports of the patients' progress and reexamine patients as frequently as desired. Dr. Rexford L. Diveley, Kansas City, is chairman of the Jackson County Medical Society's committee to serve as consultants at the institute and help formulate the medical policies.

NEW YORK

Richmond County Postgraduate Instruction.—The Medical Society of the State of New York with the cooperation of the New York State Department of Health has arranged the following lectures for the Richmond County Medical Society, to be given by New York physicians Friday afternoons at 4:30 in the auditorium of the U. S. Marine Hospital, Stapleton, Staten Island:

February 6, Dr. E. Charles Kunkle, Headache Mechanisms.
February 13, Dr. Foster Kennedy, Nervous Conditions Associated with Allergy.
February 20, Dr. S. Bernard Wortis, Recent Advances in Psychiatry.
February 27, Dr. Paul Reznikoff, Diagnosis and Treatment of Anemia.

New York City

Society News.—Dr. David Adlersberg will read a paper entitled "Newer Advances in Sprue" at the next monthly conference of the New York Institute of Clinical Oral Pathology, January 26, at the New York Academy of Medicine at 9 p. m.

Advisory Committee on Geriatrics.—An Advisory Committee on Geriatrics for the city department of health met December 19 with Dr. C. Ward Crampton as chairman. The committee expects to work in cooperation with the Joint Legislative Committee of the State of New York, which met Dec. 11, 1947 in an open hearing on age and aging, the New York State Medical Society Subcommittee on Aging and the Joint Committee on Chronic Illness of the American Medical Association.

Society News.—The pediatric section of the Kings County Medical Society and the Academy of Medicine of Brooklyn at a meeting January 26 at the county society building will present certificates of merit to the former presidents of the section who have served since reorganization in 1936. Dr. A. W. Martin Marino, president, Kings County Medical Society, will make the presentation. The guest speaker will be Dr. Harold W. Dargeon, New York, on "Neoplastic Diseases in Infancy and Childhood." The meeting will begin at 9 p. m. following a dinner given at the Unity Club in Brooklyn by the president of the pediatric section, Dr. Samuel K. Levy.

Comprehensive Health Survey.—The Health Council of Greater New York, Inc., is undertaking the "first comprehensive health survey of New York City in twenty years" as a joint venture with the Public Health Relations Committee of the New York Academy of Medicine. The purpose of the survey is to assemble data for use by the long range program committee of the health council, which is made up of representatives of fifty-five health agencies and others in allied fields in the city. The survey is being directed by Edward H. L. Corwin, Ph.D., executive secretary of the Public Health Relations Committee. It is anticipated that the work will take about two years.

NORTH CAROLINA

Medical and Surgical Symposium.—Watts Hospital, Durham, will present a Medical and Surgical Symposium February 11-12 beginning at 11 a.m. and extending through the evenings. Speakers on Wednesday's program include:

Drs. Virgil H. Moon and Garfield G. Duncan, both of Philadelphia, Clinicopathologic Conference.
Dr. Reed M. Nesher, Ann Arbor, Use of Endocrines in Management of Urogenital Tract Disease.
Dr. Louis N. Katz, Chicago, Recent Advances Concerning Coronary Heart Disease.
Dr. Lewis M. Hurxthal, Boston, Diagnosis of Pituitary Disease.
Dr. Richard B. Cattell, Boston, Pathogenesis and Treatment of Cancer of the Large Bowel.

Thursday's program includes:

Drs. Tracy B. Mallory and Conger Williams, Boston, Clinicopathologic Conference.
Dr. Nelson W. Barker, Rochester, Minn., Anticoagulant Therapy.
Dr. Ralph K. Ghormley, Rochester, Minn., Late Changes in Joints as a Result of Internal Derangements of the Knee.
Dr. Elliott P. Joslin, Boston, Treatment of Diabetes in Every Doctor's Practice.
Dr. Paul R. Cannon, Chicago, Nutritional Advances in Medicine and Surgery.

OHIO

Memorial Post.—The W. F. Bartz American Legion Post, Youngstown, established in memory of Dr. Walter F. Bartz, who lost his life in the service of his country, has received its charter. Physicians of the Youngstown area who desire membership should contact the temporary commander, Dr. Ivan C. Smith, Home Savings and Loan Building.

Dr. Edgar V. Allen Comes to Cleveland.—Dr. Edgar V. Allen, Rochester, Minn., has been appointed chief of the division of internal medicine at the Cleveland Clinic and will come to Cleveland in the near future. Dr. Allen has been with the Mayo Clinic, where he is chief of a section in the division of internal medicine and associate professor of medicine at the University

of Minnesota in the Mayo Foundation. He is a graduate of the University of Nebraska Medical School, 1925. In 1929 he studied in Germany and England as a fellow of the National Research Council, returning to the Mayo Clinic in 1930. In World War II Dr. Allen served as a colonel in the medical corps of the U. S. Army, and as consultant in medicine for the Seventh Service Command the Legion of Merit was awarded to him.

PENNSYLVANIA

Society News.—Dr. Herbert T. Kelly of Philadelphia recently presented a paper, "Nutrition—Biochemical Physiologic and Psychologic Aspects," before the Luzerne County Medical Society, Wilkes-Barre.

Open Child Guidance Center.—Announcement is made of the opening of the Child Guidance Center of Lackawanna County with offices in the Chamber of Commerce Building, Scranton. This center is a community project for the purpose of consultation, treatment and training. Dr. Samuel A. Guttman is serving as director.

Philadelphia

Hospital News.—The Skin and Cancer Hospital of Philadelphia announces the association of the respective professors of dermatology and syphilology of the University of Pennsylvania and Temple University, Dr. Donald M. Pillsbury and Dr. Carroll S. Wright, as co-medical directors of the hospital. The responsibility for the professional care of outpatients and inpatients in the hospital has been delegated to these two services, and a considerable number of new appointments to the attending and consultant staffs have already been made.

Ten New District Health Centers.—Ten consolidated health centers, each to be situated in a district of 200,000 inhabitants, are being set up by the Department of Public Health of Philadelphia. Each center will house a child health center, dental clinic, chest clinic, venereal disease clinic and offices for the inspectors for the district from the Divisions of Housing and Sanitation and of Milk, Livestock, Meat and Food. On Oct. 14, 1947 the city council appropriated seven tracts of land with the buildings erected on them for use as District Consolidated Health Centers. One property has not as yet been selected. One center at 20th and Berks streets, manned entirely by Negro physicians and nurses, is complete. In addition there are twelve child health centers in rented quarters, thirteen chest clinics and fourteen venereal disease clinics.

WISCONSIN

Bardeen Memorial Lecture.—The Dr. Charles R. Bardeen Memorial Lecture will be delivered by Dr. George W. Bartelmez, professor of anatomy, University of Chicago, at 8 p.m. February 17 in the auditorium of the Service Memorial Institutes, Madison. This annual lectureship is sponsored by Phi Chi Medical Fraternity at the University of Wisconsin. Dr. Bardeen was the first dean of the Wisconsin Medical School, serving in that capacity from 1907 until his death in 1935. In addition, he was professor of anatomy in the medical school.

Research Group Presents Program.—The Cancer Research Group, associated with the McArdle Memorial Laboratory of the University of Wisconsin Medical School, Madison, presented the scientific program for the January meeting of the University Medical Society January 6. The McArdle Memorial Laboratory is one of eight similar institutions in the United States which is devoting full time study and investigative research to the problems of cancer. Dr. Harold P. Rusch is director of the group. The meeting was open to all persons interested in the subject of cancer.

FOREIGN

Society Election.—At the annual meeting of the Royal College of Physicians of Edinburgh, Scotland, Dec. 4, 1947 Dr. William D. D. Small was elected president.

Cholera in Syria and Lebanon.—The *New York Times* reports an outbreak of cholera in two Syrian villages, where 53 cases and 15 deaths had been officially reported on Dec. 23, 1947. Only medical personnel, food convoys and a train carrying water from Damascus to replace water from infected wells were allowed to enter the city. The mayor of Damascus announced that a daylong curfew would be imposed successively on each of four sections of the city while all inhabitants underwent compulsory vaccination. The Syrian government prohibited all departures from Damascus or the Hauran district unless the travelers held certificates of inoculation at least three days old and not older than one month. Air travel between Syria, Lebanon and Iraq was suspended. Two cholera specialists arrived from Egypt with 296,000 bottles of vaccine and enough was en route to inoculate more than 1,000,000 persons.

GENERAL

Postgraduate Assembly in Endocrinology.—The Association for the Study of Internal Secretions will hold a Postgraduate Assembly in Endocrinology in Los Angeles February 23-28. The faculty is composed of outstanding students of endocrinology in the United States and Canada. Applications may be sent to Dr. E. Kost Shelton, chairman, Committee on Postgraduate Instruction, 921 Westwood Boulevard, Los Angeles 24.

Decline in Mortality from Toxic Goiter.—The *Statistical Bulletin* of the Metropolitan Life Insurance Company reports a 40 per cent reduction in the mortality from toxic goiter among its industrial policyholders in the period from 1940 to 1947. The adjusted death rate from this cause at ages 1 to 74 years declined from 1.9 per 100,000 in 1940 to 1.1 in 1946. In 1945 there were 2,468 deaths from toxic goiter in the general population of the United States as compared with 3,659 in 1940.

Special Society Elections.—The National Medical Association installed Dr. J. A. C. Lattimore, Louisville, Ky., as president and chose Dr. C. Austin Whittier, San Antonio, Texas, president-elect; John T. Givens, Norfolk, Va., secretary, and Eugene T. Taylor, St. Louis, treasurer, at a recent meeting in Los Angeles. At the annual meeting of the American Academy of Dermatology and Syphilology in Chicago, December 6-11, Clyde L. Cummer, Cleveland, was elected president, Francis E. Seneac, Chicago, vice president, and Earl D. Osborne, Buffalo, secretary-treasurer. The American Association for the Advancement of Science at its meeting in Chicago Dec. 26, 1947 chose Dr. Elvin C. Stakman, Ph.D., of St. Paul as president-elect. Among sectional vice presidents is Dr. Shields Warren, Harvard University, Boston, chairman of the medical sciences section.

Meeting of Surgeons of the Hand.—The American Society for Surgery of the Hand will meet at Thorne Hall, Northwestern University, Chicago, January 23-24 beginning at 9 a.m. Speakers on the program, which is entirely clinical, will be Drs. Condit W. Cutler, Jr., New York; Colin G. Thomas, Iowa City; John W. Kirklin, Rochester, Minn.; William H. Frackelton, Milwaukee, Wis.; Clarence A. Luckey, Oakland, Calif.; Michael L. Mason, Sumner L. Koch and Harvey S. Allen, Chicago; Rufus H. Alldredge, New Orleans; J. William Littler, New York; Lieut. Col. Gilbert L. Hyroop, MC, Battle Creek, Mich.; Walter C. Graham, Santa Barbara, Calif.; Daniel J. Riordan, Buffalo; Sterling Bunnell, San Francisco; Donald B. Slocum, Eugene, Ore.; and C. Hunter Sheldon, Pasadena, Calif. The society dinner will be held Friday, 6:30 at the University Club.

Society News.—The National Society for Crippled Children and Adults, Inc., which met in Chicago November 2-5, reelected Col. E. W. Palmer, Kingsport, Tenn., president, and Lawrence J. Linck, Chicago, secretary. Five states (Washington, Oregon, Montana, Rhode Island and North Dakota) and Hawaii became new members of the society. At the annual meeting of the Association of State and Territorial Health Officers in Washington, D. C., December 1-4, attended by representatives of forty-eight states and territories, Dr. Vlado A. Getting, Boston, was elected president and Dr. Leroy E. Burney, Indianapolis, secretary-treasurer. The Southern Medical Association at its recent meeting in Baltimore chose Dr. Oscar B. Hunter, Washington, D. C., president-elect, and Dr. David G. Miller Jr., Morgantown, Ky., secretary. Dr. George E. Burch, Tulane University of Louisiana School of Medicine, New Orleans, was presented the association's research medal "in recognition of his valuable contribution to the understanding of cardiovascular disorders."

Award of the Strong Medal.—The American Foundation for Tropical Medicine presented the fifth annual Richard P. Strong Medal for Distinguished Service to Tropical Medicine to Dr. Neil P. Macphail, veteran surgeon and sanitarian of the United Fruit Company at Guirigua, Guatemala, at its annual dinner in New York January 8. Among the speakers were Major Gen. Raymond W. Bliss, Surgeon General, U. S. Army; Admiral Thomas C. Kinkaid, commander, Eastern Sea Frontier, and the Hon. Dr. Francis P. Corrigan, advisor to the United States Mission to the United Nations.

Dr. Macphail has been active in tropical medicine in Middle America since 1907, when he accepted a position as quarantine doctor for the port of Belize, British Honduras. The following year he became medical superintendent of the United Fruit Company's east coast division of Guatemala, a position he still holds. During the past forty years his efforts in combating yellow fever, cholera, endemic malaria, dysenteries, snake bite, night blindness and other tropical maladies have earned for him the name *el amado medico* (the beloved doctor).

Graduate Courses in Thoracic Diseases.—The American Trudeau Society and the medical section of the National Tuberculosis Association are offering two and four week postgraduate courses in thoracic diseases in four sections of the country during the early part of 1948. 1. The course for Ohio, Indiana, Michigan, Illinois, Wisconsin, Missouri, Iowa and Minnesota will be held at Herman Kiefer Hospital, Detroit, March 22-26 in cooperation with the Detroit Department of Health and Wayne University College of Medicine. Dr. Paul T. Chapman, Herman Kiefer Hospital, is chairman, and the registration fee is \$50. 2. For Maryland, District of Columbia, Virginia, West Virginia, Kentucky, Tennessee, North Carolina, South Carolina, Georgia and Florida, the course will be at Durham, N. C., March 22-27 in cooperation with the medical schools of the University of North Carolina, Chapel Hill, and Duke University, Durham. The chairman is Dr. Henry S. Willis, North Carolina Sanatorium, Sanatorium, N. C., and the registration fee is \$50. 3. For Maine, Vermont, New Hampshire, Massachusetts, Connecticut and Rhode Island, the course will be in Boston April 5-17 in cooperation with the medical schools of Harvard University, Tufts and Boston University under the chairmanship of Dr. Theodore L. Badger, 264 Beacon Street, Boston. The registration fee is \$100. 4. The course for Alabama, Arkansas, Louisiana, Mississippi, Oklahoma and Texas will be April 12-24 in Dallas, Texas, under the chairmanship of Dr. Julius L. Wilson, 1430 Tulane Avenue, New Orleans 13. The fee is \$100.

Report on Cholera in Egypt.—The World Health Organization in its November *Chronicle* published a report of the first eight weeks of the cholera epidemic in Egypt. Four cases occurred simultaneously at El Kuein and spread through the neighboring provinces in Lower Egypt and to the canal ports of Ismailia and Suez. In the third week all Delta provinces were infected, but in Upper Egypt the disease remained confined to Giza. During the fourth week the incidence rose to a twenty-four hour peak figure of 1,022 with 581 deaths, and in Upper Egypt the total for the week was 4,566 cases with 2,057 deaths. The epidemic reached its greatest height during the fifth week, with 5,976 cases and 2,933 deaths. Suez alone was cholera free. The sixth week showed the first indications of the decline of the epidemic. By the seventh week cases had declined to 2,218, and of the four thousand villages considered infected, when the epidemic was at its height, only eighty-eight remained infected. During the eight weeks under review the epidemic produced 20,877 cases with 10,265 deaths, a case fatality of 49.16 per cent. In 1902 when Egypt had its last previous epidemic there were 40,613 cases and 34,595 deaths, a fatality rate of 85 per cent. The present population of Egypt is almost double that of 1902. The *Chronicle* reports that in spite of repeated re-introduction from villages the disease failed to establish itself in any town provided with satisfactory water supplies and adequate disposal systems. As soon as 80 per cent of the population had received anticholera vaccine, the over-all incidence began to fall, although the decrease came at the time of the spontaneous autumnal decline characteristic of each previous outbreak of cholera in Egypt.

CORRECTION

Dosage of Acetylsalicylic Acid.—In the abstract entitled: "Succinate-Salicylate Therapy in Arthritis" in THE JOURNAL, Dec. 20, 1947, page 1114, the dosage of acetylsalicylic acid should be 45 grains (2.91 Gm.) instead of 45 Gm.

Marriages

DANIEL GEDDIE MONROE, Fayetteville, N. C., to Miss Bette Thomas Sampson of Bennettsville, S. C., Oct. 4, 1947.

JOHN ALEXANDER BENSON Jr., Windsor, Conn., to Miss Irene Zucker of Fort Myers, Fla., recently.

JOSEPH FRASIA JONES Jr. to Miss Henrietta Short Tabb, both of Richmond, Va., Nov. 8, 1947.

JOSEPH FLOYD HOCOTT, Abilene, Texas, to Miss Betty Gwen Barlow, in New York, Nov. 24, 1947.

JEROME K. BURTON to Mrs. Marguerite Whisman Riordan, both of Boise, Idaho, Sept. 23, 1947.

JOHN EDWARD SMITH, Fitzgerald, Ga., to Mrs. Anne Shelton Roberts in Atlanta, Oct. 11, 1947.

JAMES E. FORSYTH, Battle Creek, Mich., to Miss Winifred Backman of St. Joseph, recently.

JOHN M. LANGSTAFF, Fairbury, Ill., to Miss Ruth A. Ford of Chatsworth, Oct. 6, 1947.

Deaths

James Chambers Pryor * Medical Director, Rear Admiral, U. S. Navy, retired, Brooklyn; born in Winchester, Tenn., on March 13, 1871; University of Nashville Medical Department and the Vanderbilt University College of Medicine in Nashville in 1894; entered the Navy in March 1897; veteran of the Spanish-American War; at various times served at the Naval Medical School and the Naval Hospital in Washington, D. C., the Norfolk Navy Yard, the Naval Hospital at Annapolis and as fleet surgeon and aid on the staff of the commander of the United States fleet; formerly medical officer at the first district in Boston; commanding officer of the Naval Medical Supply Depot in Brooklyn when he retired in 1935; fellow of the American College of Surgeons; past president of the Association of Military Surgeons of the United States; delegate to the International Congress of Military Medicine and Pharmacy serving once at The Hague and again in Brussels; formerly professor of preventive medicine at George Washington University School of Medicine in Washington, D. C.; attending physician at the White House during the administration of President Theodore Roosevelt; author of "Naval Hygiene"; formerly editor of the *Naval Medical Bulletin*; died in the Naval Hospital Sept. 8, 1947, aged 76, of arterial hypertension.

Richard Henry Hutchings * Utica, N. Y.; born in Clinton, Ga., Aug. 28, 1869; Bellevue Hospital Medical College, New York, 1891; lecturer on psychiatry and clinical professor of psychiatry at the Syracuse University College of Medicine from 1908 to 1934, when he became emeritus clinical professor; served during World War I; specialist certified by the American Board of Psychiatry and Neurology; member and past president of the American Psychiatric Association; member of the American Psychoanalytic Association; for many years superintendent of St. Lawrence State Hospital in Ogdensburg and Utica State Hospital; served as editor of the *Psychiatric Quarterly*; died in Clinton, Ga., Oct. 28, 1947, aged 78, of cerebral hemorrhage.

Henry Milligan Chandler * Orangeburg, N. Y.; born in South Orange, N. J., Sept. 15, 1879; Albany (N. Y.) Medical College, 1903; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the American Psychiatric Association; associate director of the Rockland State Hospital; at various times affiliated with the New Jersey State Village for Epileptics, Skillman, N. J., Manhattan State Hospital in New York, Southeastern Hospital for the Insane, Madison, Ind., Connecticut State Hospital in Middletown, Blythewood Sanatorium, Greenwich, Conn., Utica (N. Y.) State Hospital and Kings Park (N. Y.) State Hospital; died in St. Luke's Hospital, New York, Oct. 19, 1947, aged 68, following an operation for gallstones.

Harry Raphael Jerome Kelly, Weehawken, N. J.; born in New Orleans, June 25, 1899; University of Virginia Department of Medicine, Charlottesville, 1931; member of the American Medical Association; a major in the medical corps, Army of the United States, during World War II, receiving official commendation from the British government and from the chiefs of staff of the U. S. Army for his care of liberated prisoners of war from the Pacific area; chief of the medical service of St. Mary's Hospital in Hoboken and chief of the chest clinic at St. Vincent's Hospital in New York, where he died Oct. 17, 1947, aged 48, of coronary thrombosis.

Leon Alphonse Martel * Washington, D. C.; Georgetown University School of Medicine, Washington, 1908; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; professor of gynecology and director of the department at his alma mater; fellow of the American College of Surgeons; on the staff of Georgetown University and Gallinger Municipal hospitals; served during World War I; past president of the Georgetown Clinical Society and the Washington Gynecological Society; died Oct. 11, 1947, aged 64, of coronary sclerosis and hypertension.

Clifford Reeder Hervey, St. Petersburg, Fla.; born in Mount Vernon, Ohio, Aug. 14, 1867; University of Michigan Homeopathic Medical School, Ann Arbor, 1893; joined the state department of health in New York as sanitary supervisor in 1917, a title later changed to district state health officer in 1923; on August 31, 1937, retired after twenty years in the health service of the state; at one time served on the board of managers of the Oswego County Sanatorium in Richland, N. Y., and member of the city board of health and Civil Service Board in Oswego; died Oct. 16, 1947, aged 80, of coronary occlusion.

Cassius D. Alexander, Vaiden, Miss.; Memphis (Tenn.) Hospital Medical College, 1900; past president of the school board; formerly county health officer; served overseas during World War I; died Oct. 17, 1947, aged 73, of heart disease.

Jarvis Lee Anderson * Manchester, Ky.; Kentucky School of Medicine, Louisville, 1897; served as vice president and member of the board of directors of the First National Bank of Manchester; died Oct. 16, 1947, aged 76, of angina pectoris.

William Coleman Armstrong * Windsor, N. Y.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1893; served as a member of the school board; vice president and director of the Windsor National Bank; died in the Binghamton (N. Y.) City Hospital Oct. 11, 1947, aged 78, of chronic myocarditis.

Arthur Monroe Barrows * Trenton, N. J.; Jefferson Medical College of Philadelphia, 1901; affiliated with the Mercer Hospital, where he died Oct. 10, 1947, aged 71, of coronary thrombosis.

Frank Tully Bascom, Rochester, N. Y.; Hahnemann Medical College and Hospital of Philadelphia, 1901; surgeon for the New York Central and Pennsylvania railroads; affiliated with Genesee Hospital and Highland Hospital, where he died Oct. 21, 1947, aged 71, of heart block and cerebral hemorrhage.

Ewald George Baum * Wellesley, Mass.; George Washington University School of Medicine, Washington, D. C., 1911; served on the staff of Leonard Morse Hospital in Natick; died in Canaan, N. H., Oct. 22, 1947, aged 62, of coronary thrombosis.

John Columbus Belue, Rogersville, Ala. (died in Alabama in 1890); died Oct. 14, 1947, aged 89, of heart disease.

Charles Percy Bonham, Barton, N. Y.; Syracuse University College of Medicine, 1906; formerly practiced in Buffalo; died in Tioga County General Hospital in Waverly, Oct. 4, 1947, aged 66, of pneumonia, subarachnoid hemorrhage and Parkinson's disease.

Kawilins Cadwallader, San Francisco; University of California Medical School, San Francisco, 1893; formerly on the faculty of his alma mater; at one time affiliated with the U. S. Public Health Service Reserve; served during World War I; author of "Hand-Book of Obstetrics"; died in Palo Alto Oct. 12, 1947, aged 81, of diabetes mellitus.

William Mack Capehart, Greenville, N. C.; Meharry Medical College, Nashville, Tenn., 1915; died Oct. 12, 1947, aged 63, of cardiovascular renal disease.

Joseph Harvey Chance, Detroit; Chicago College of Medicine and Surgery, 1914; member of the American Medical Association; served during World War I; died in the Lincoln Hospital Oct. 26, 1947, aged 59, of hypertensive heart disease.

Robert Brigham DeLong, Worcester, Mass.; McGill University Faculty of Medicine, Montreal, Canada, 1941; served in the Pacific and in Leyte during World War II; interned at the Montreal General Hospital in Montreal and the Worcester City Hospital, where he died Oct. 14, 1947, aged 34.

Vivian Inez Douglas, Newark, N. J.; Meharry Medical College, Nashville, Tenn., 1947; received an appointment as an intern at the Lincoln Hospital in Durham, N. C.; died in the Newark Eye and Ear Infirmary Oct. 14, 1947, aged 27, of spinal meningitis.

Howard Trivers Exley, Savannah, Ga.; Atlanta College of Physicians and Surgeons, 1911; member of the American Medical Association; affiliated with the Warren A. Candler Hospital, where he died Oct. 22, 1947, aged 58, of heart disease.

Walter Chester Hart, McComb, Miss.; Memphis (Tenn.) Hospital Medical College, 1908, member of the American Medical Association; died in the McComb Infirmary Oct. 26, 1947, aged 65, of coronary occlusion.

John Hampton Holcomb, Hepburn, Ohio; College of Physicians and Surgeons, Baltimore, 1892; for many years county health officer; died Oct. 23, 1947, aged 81, of coronary thrombosis.

David Isaac Hirsch * Monroe, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1908; formerly vice president of the Louisiana State Medical Society; past president of the Quachita Parish and Fifth District medical associations; past president of the Louisiana Gynecological Society; served during World War I; affiliated with St. Francis Sanitarium and the E. A. Conway Memorial Hospital; for many years president of the city board of health; died Oct. 21, 1947, aged 60, of coronary occlusion.

William Newton Kenzie * Richland, Mich.; Illinois Medical College, Chicago, 1900; served during the Spanish-American War and World War I; for many years affiliated with the

Veterans Administration Facility at Fort Custer; died in Borgess Hospital, Kalamazoo, Oct. 19, 1947, aged 72, of carcinoma of the penis with metastasis.

Oscar Wentworth King ☉ Coral Gables, Fla.; University of Maryland School of Medicine, Baltimore, 1907; member of the Medical Society of the State of New York; specialist certified by the American Board of Ophthalmology; served during World War I; formerly on the staff of the Eye and Ear Hospital in Brooklyn; died Oct. 16, 1947, aged 63, of coronary artery disease.

Otto Marvin La Core, Empire, Mich.; Tennessee Medical College, Knoxville, 1901; Saginaw (Mich.) Valley Medical College, 1902; for many years city physician at Muskegon Heights; affiliated with Hackley Hospital in Muskegon, where he died Oct. 17, 1947, aged 72, of cerebral hemorrhage.

Edward Levy, Brightwaters, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1900; died Oct. 10, 1947, aged 69, of carcinoma.

Mary H. McKee, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1888; for many years attached to the Indian Service; died Oct. 10, 1947, aged 81, of chronic myocarditis.

Elmer Eason McKeown ☉ Denver; Denver and Gross College of Medicine, 1905; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; affiliated with St. Luke's, St. Joseph's, Children's and Colorado General hospitals; died Oct. 7, 1947, aged 67, of cerebral vascular accident.

Alfred Lawrence Madden ☉ Albany, N. Y.; Albany Medical College, 1919; associate professor of obstetrics at his alma mater; specialist certified by the American Board of Obstetrics and Gynecology; attending obstetrician and chairman of the staff, Brady Maternity Hospital; died Oct. 18, 1947, aged 51, of coronary thrombosis.

James Rollin Manley ☉ Duluth, Minn.; born in Bellona, N. Y., March 21, 1885; University of Minnesota College of Medicine and Surgery, Minneapolis, 1908; member of the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; specialist certified by the American Board of Obstetrics and Gynecology; affiliated with the Miller Memorial Hospital, St. Mary's Hospital and St. Luke's Hospital, where he died Oct. 21, 1947, aged 62, of coronary occlusion.

Albert Howell Mann, Texarkana, Ark.; Tulane University of Louisiana School of Medicine, New Orleans, 1926; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and the American Medical Association; died Oct. 16, 1947, aged 48, of hypertension.

Charles Hamilton Medders, Still Pond, Md.; University of Maryland School of Medicine, Baltimore, 1894; died Oct. 6, 1947, aged 75, of carcinoma.

Charles Hope Merz, Sandusky, Ohio; University of Wooster Medical Department, Cleveland, 1885; member of the American Medical Association; editor and publisher of the *Sandusky Masonic Bulletin* for many years; affiliated with Providence Hospital and the Good Samaritan Hospital, where he died Oct. 14, 1947, aged 85, of heart disease.

Joseph Arthur Minus, Epes, Ala.; Birmingham Medical College, 1908; member of the American Medical Association; died Oct. 7, 1947, aged 65, of coronary thrombosis.

John Garnet Moir ☉ Deming, N. Mex.; Central College of Physicians and Surgeons, Indianapolis, 1898; vice president of the Mimbres Valley Bank; died Oct. 11, 1947, aged 80, of coronary thrombosis.

Terrell Moody, Washington, D. C.; George Washington University School of Medicine, Washington, D. C., 1923; served during World War I; died in Palatka, Fla., Oct. 25, 1947, aged 50, of heart disease.

Ernest Ivan Mulder, Compton, Calif.; College of Medical Evangelists, Los Angeles, 1920; fellow of the American College of Surgeons; member of the American Medical Association; affiliated with Las Campanas Hospital in Compton and St. Francis Hospital in Lynwood, where he died Oct. 6, 1947, aged 53, of lymphosarcoma.

Augustine Joseph Mulligan, Philadelphia; University of Louisville Medical Department, 1911; served during World War I; on the staff of St. Agnes' Hospital; died in St. Joseph's Hospital Oct. 2, 1947, aged 59, of hemorrhage of the stomach.

Frank Hermann Munkwitz ☉ Milwaukee; Bellevue Hospital Medical College, New York, 1890; also a graduate in pharmacy; member of the medical advisory board during World

War I; on the staffs of Children's Hospital, St. Mary's Hospital and the Columbia Hospital, where he died Oct. 18, 1947, aged 79, of arteriosclerosis.

Frank Thomas Murphy, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; on the staff of Garfield Park Community Hospital; died Oct. 15, 1947, aged 67, of carcinoma of the stomach.

Joseph Leon Page, Philadelphia; Howard University College of Medicine, Washington, 1928; interned at St. Agnes' Hospital in Raleigh, N. C.; died recently, aged 46, of biliary cirrhosis.

Thomas Lloyd Paton, East Paterson, N. J.; College of Physicians and Surgeons, Baltimore, 1887; for many years city physician and medical inspector of public schools; for two years president of the board of health; affiliated with Paterson General and St. Joseph's hospitals in Paterson; died Oct. 6, 1947, aged 94, of hypostatic pneumonia.

Leverett Francis Pelton, Cleveland; Cleveland University of Medicine and Surgery, 1883; died recently, aged 86, of cerebral embolism.

Edwin Thomas Redmond ☉ Brooklyn; Eclectic Medical College, Cincinnati, 1916; for many years on the staff of the Prospect Heights Hospital and the Brooklyn Infants Hospital; died Oct. 8, 1947, aged 54.

Morris Hamilton Reno ☉ Canton, Ohio; Ohio State University College of Homeopathic Medicine, Columbus, 1918; served during World War I; on the staff of the Aultman Hospital; died in East Side Hospital, Pittsburgh, Oct. 26, 1947, aged 56, of injuries received when he fell down the stairs.

William Truman Sharpless, West Chester, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1888; member of the American Medical Association; past president of the Medical Society of the State of Pennsylvania and the Chester County Medical Society; affiliated with Chester County Hospital; died Oct. 19, 1947, aged 91.

Byron Grant Sherman ☉ Morristown, N. J.; University and Bellevue Hospital Medical College, New York, 1921; fellow of the American College of Surgeons; on the staff and president of the medical board of Morristown Memorial Hospital and on the staff of All Souls Hospital; died Oct. 10, 1947, aged 60, of coronary thrombosis.

James Garfield Slater, St. Petersburg, Fla.; Hospital College of Medicine, Louisville, 1904; affiliated with St. Elizabeth's Hospital in Covington, Ky.; died Oct. 26, 1947, aged 65, of coronary thrombosis.

John Robert Thompson Snyder ☉ Altoona, Pa.; Jefferson Medical College of Philadelphia, 1915; fellow of the American College of Surgeons; served during World War I; affiliated with the Altoona Hospital; died Sept. 15, 1947, aged 56, of coronary thrombosis.

Harold Eugene Weller ☉ St. Petersburg, Fla.; University of Pittsburgh School of Medicine, 1916; died Oct. 8, 1947, aged 56.

Charles Edward West, Homestead, Fla.; Chicago Homeopathic Medical College, 1898; formerly a medical missionary; served overseas during World War I; died in a hospital at Nampa, Idaho, Sept. 13, 1947, aged 74, of carcinoma of the stomach.

William Davidson Wheeler, Brookline, Mass.; Tufts College Medical School, Boston, 1918; also a pharmacist; affiliated with Beth Israel Hospital and Boston Dispensary in Boston; died Oct. 10, 1947, aged 57, of coronary heart disease.

Joel Whitaker, Indianapolis; University of Maryland School of Medicine, Baltimore, 1910; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served on the staffs of Methodist Hospital and St. Vincent's Hospital, where he died Oct. 13, 1947, aged 70, of cardiac failure and pulmonary edema.

William C. F. Witte ☉ Milwaukee; Rush Medical College, Chicago, 1896; fellow of the American College of Surgeons; served as clinical professor of surgery at the Marquette University School of Medicine; for many years affiliated with St. Mary's Hospital, where he died Oct. 10, 1947, aged 78, of coronary thrombosis.

Henry E. Wunder, Shakopee, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1892; member of the American Medical Association; died in Milwaukee Oct. 14, 1947, aged 76, of carcinoma of the pancreas.

Nathan Zommick ☉ New York; Long Island College Hospital, Brooklyn, 1913; died in Beth David Hospital Oct. 13, 1947, aged 63, of arteriosclerosis.

Dec. 6, 1947.

The Future of Denominational Hospitals

The intention of the government to take over and administer all the hospitals under the National Health Service is meeting with opposition. A meeting of Roman Catholic physicians and representatives of the managing bodies of Roman Catholic hospitals was held in London. Cardinal Griffin, Archbishop of Westminster, said that the National Health Service Act should be amended to safeguard the rights of denominational hospitals and similar institutions. Some Roman Catholic hospitals were outside the provisions of the act, and others would claim exemption. There must be a guarantee that these should be able to preserve their Catholic nature, have a Catholic management committee and be allowed to admit Catholic patients. Religion has always played an important part in the care of the sick, and nursing is not merely a profession but also a vocation.

Petrol Concessions to Doctors

Among the restrictions imposed by the government in order to deal with the dollar shortage is forbidding the use of automobiles for private purposes, thus reducing the consumption of petrol. But it became apparent that this would impose a hardship on doctors, who differ from other members of the community in that they are normally on call by patients at all times of the day and night. Indeed, they are dependent on their automobiles for a few hours' relaxation from their practices, because the car is part of their essential medical equipment which must be immediately available for an emergency call. Representations were therefore made to the Minister of Fuel and Power by the General Practice Committee of the British Medical Association that a doctor when on call by his patients should be permitted to use his car for any purpose. While recognizing the special difficulties of the doctor, the Minister could not agree that the physician should not be subject to some form of restriction in the use of petrol. But he agreed that if a doctor undertakes a social or recreational engagement and is at that time on call to his patients he should be allowed to use his car. In these circumstances he must be able to justify his action to the police. This he could not do if he had made alternative arrangements for attendance on his patients. The concession was also obtained that petrol may be allowed to doctors for the purpose of attending meetings of the British Medical Association or other professional meetings in their locality.

Bill to Install Refugee Doctors on the Medical Register

In the House of Commons the second reading of a bill for the registration of the foreign refugee doctors, who came here during the war and rendered valuable service to this country in that period of difficulty and danger, was carried with unanimous approval. Mr. Bevan, Minister of Health, said that these doctors, who were allowed to practice here under Defence Regulation 32 b during the war, would be unable to practice after December 31 unless their position were regularized. The bill would do this and put them in the same position as British doctors with the ordinary British qualifications. There would be about 3,500 such doctors when the register was closed, but he did not believe that all would want to remain. It was estimated that between 1,500 and 2,000 would want to avail themselves of the facilities afforded by the bill. Polish doctors brought here under the Polish resettlement scheme numbered

about 200, and it was expected that this figure would have to be increased by the end of the year.

Provision was also made for foreign doctors who served with British forces overseas and who on demobilization had been permitted to enter the country. Special arrangements would have to be made to deal with physicians attached to the Polish forces who could not be in this country before the end of the year. Mr. Bevan proposed to introduce an amendment in committee to enable doctors attached to our establishments abroad to practice in this country. Mr. Bevan added that the medical profession had benefited enormously from doctors who had fled from other countries and had come here. We needed more facilities for postgraduate medical training in this country and in the commonwealth generally.

Supersonic Reproduction on Gramophone Records

For the first time in the history of acoustics frequencies up to 20,000 cycles per second are now being reproduced on gramophone records. Sir Ernest Fisk, managing director of Musical Industries Ltd., announced this as a meeting of the Royal Society of Arts. In terms of electrical reproduction this means that every note and tonal characteristic detectable by the human ear in an original performance can now be heard with equal fidelity from a gramophone record. While the upper frequency response limit of the human ear varies enormously, not only from person to person but according to age, few can detect notes of frequencies higher than about 15,000 or 16,000 cycles a second. The significance of reproduction as high as 20,000 cycles is a safety margin beyond the top limit of human hearing for supersonic transients which affect the tonal character of sounds within the audibility range.

A New Principle for the Administration of Antibiotics

For six months, Professor Mollaret, at the Claude-Bernard Hospital, has used a new method of treatment (for pyogenic meningitis, septicemia, tonsils phlegmon and the like) consisting in a realization, as rapidly as possible, of the antibiotic concentration without ever reducing the dose, which will render probable the desired sterilization and then an abrupt cessation of administration of penicillin. At the first sign of relapse the treatment is resumed at a double dose. The author has met with success with this method. He is now studying two new technics, one consisting in the administration of a double dose of the antibiotic on the eve of cessation of the treatment, in order to give a finishing stroke to the resisting microbes. He is also trying to obtain a penicillinase, by preference crystallized, for administration to human beings. The research on penicillinase is effected in the laboratory of Professor Trefouel, director of the Pasteur Institute. Hormones, vagomimetics and sympatheticomimetics are substitutive medicaments, with which the point is to cease administering by stages in order to permit the body to regain progressively its equilibrium. To the contrary, anti-infectious medicaments are to be used as radical treatment.

Treatment of Cancer of Esophagus

Nuboer (Utrecht), an advocate of cyclopropane-curare anesthesia in surgery of the esophagus, insists on the necessity of "hydrating" and "proteinizing" the patient and of administering quinine in order to avoid auricular fibrillation in aged patients. The author bewares of the vascularization of the superior part of the gastric tube, after ablation of the tumor. He resects it and performs terminal anastomosis. R. H. Sweet (Boston) sent a beautiful color film of low esophagectomy with esogastric anastomosis; several other films were also presented: one from

John Garlock (New York) on the surgical treatment of cancer of the thoracic esophagus; two from J. Blalock (New York), one on the surgical treatment of stricture of the pulmonary artery, the other on the surgical treatment of aortic stricture; one from Lelio-Zeno (Rosario, Argentina) on prethoracic esophagoplasty; Waltman Walters (Rochester, Minn.) presented a series of radiographic films showing the different conditions of the biliary ducts under the influences of hypertensive or hypotensive medicaments. Xavier Gelle showed one film on the Hallux Valgus operative technic; M. Montant (Paris), another on his technic of esthetic surgery of the breasts; René Charry (Toulouse), on the technic of arthroplasty of the elbow.

The next congress will take place in Paris on Oct. 4, 1948 under the presidency of Jean Fiolle (Marseille), the vice president being Paul Mathieu (Paris).

Painful Limb Stumps

In his study of 1,000 cases Dessaint (Rouen) has noted a striking parallel between the painful rhythms and the course of gastric ulcers. The fact that pain in amputated patients affected with neuroma appears at fixed hours seems to be due to a trouble of the chemical transmission of the nerve impulse, in a bad liberation of acetylcholine and vitamin B₁ against the potassium ion at the very level of the points of transmission, which liberation is impaired by too numerous excitations. For treatment, David, Hecan and Talairach begin with a minimal sympathetic intervention. On account of the progression of pain along the sensitivity tracts up to the cortex cerebri, the isolation of the periphery from the central nervous system is necessary, and this is to be performed at the posterior root by cutting one or two roots only. As regards the phantom limb, they contemplate an intervention on the parietal cortex after a previous electroencephalography; they consider prefrontal lobectomy as an ultimate therapy. Fontaine and Frank (Strasbourg) present their observations on 585 cases. Of 82 per cent of the amputated patients who suffer more or less, only 6 per cent have totally painful stumps, 12 per cent of which are from civil practices, 6 per cent from the first world war and 4 per cent from the second; pain is more frequent in the amputations due to traumatism (14 per cent) than in those due to arteritis (6 per cent). As the best treatment, they consider an intervention on the sympathetic combined with the resection of a bad cicatrix. In place of radiculomedullary interventions that have given only poor results, the authors propose to resort directly to cerebral interventions. Jung (Strasbourg) in his study of 27 patients having an exact notion of their phantom limb has found that the shorter the stump, the longer the phantom. There seems to be a psychic phase to the phantom: its length is constant when at rest and is shortened by the suspension of a weight to the stump, even to the artificial limb, and by infiltration of procaine but is lengthened after a stellate infiltration.

Congress of the French Surgery Association

The fiftieth congress of the French Surgical Association took place Oct. 6 to 10, 1947 under the presidency of Dr. Baumgartner and was attended by a large number of French and foreign surgeons. The United States was represented by Earl Walker (Chicago), Garlock, Blalock and Ramsell (New York), Waltman Walters (Rochester, Minn.) and Hermann (Cincinnati); Argentina by Lelio Zeno, Mirizze and Resano. Among the numerous European countries, Belgium was represented, beside others, by Danis, Mayer, Spehl, Lambotte and Dejardin; Switzerland by Julliard, Decker, Pettavel and others; the Netherlands by Nuboer and Koch. Among numerous personalities at the opening meeting were Professor Hartmann, president of the French Surgery Association, Professor Sarailh, vice chancellor of the university, Professor Binet, dean of the faculty, Dr. Georges Duhamel, of the French Academy, and Dr. Rist, president of the National Academy of Medicine.

Death of Professor P. L. Simond

Professor Simond died at the age of 89 at Valencia (Drôme). He studied microbiology at the Pasteur Institute. In 1896 and 1897 he accomplished important work in Mecknikoff's laboratory on the evolution of parasites. In 1898, while in India to study the great epidemic of plague, then prevalent at Bombay, he delivered the experimental proof of the virus transmission of plague by flea bites from a dying rat to a healthy one, which permitted him to insure the prophylaxis of plague. In 1906 he was appointed vice director of the Marseilles Colonial School, where he taught microbiology; in 1911 he became director of the Constantinople Institute of Bacteriology. He ended his career as chief of the health service of Indo-China from 1914 to 1917. He then retired and devoted himself to social work.

BERLIN

(From Our Regular Correspondent)

Dec. 6, 1947.

The Tuberculosis Situation in Germany

The first peak of the tuberculosis death rate in Germany in this century was reached during World War I. In 1917 it was 32.3 per ten thousand population per annum. Between the two wars the situation improved steadily. An all time low was reached in 1938 with a death rate of 8.2. Exact records for the time of World War II do not exist. Owing to the political situation, even now central German statistics are not available, but local and zonal statistics offer good substitutes. In 1945 the tuberculosis death rate for Germany was as high as 28.6, which about equals the figure of 1919. From then on, the situation has improved to some extent, and the death rate in the fall of 1947 was down to 24.8. But the over-all picture of this year will nevertheless not be favorable, because many more new cases have been reported in the fall of this year than in the corresponding months of 1946. The number of deaths due to tuberculosis all over Germany in 1946 and 1947 is estimated as between 150,000 and 200,000 per year. In Berlin the figure is about 8,000 per year, and Berlin autopsy figures (Koch) for the second half of 1945 and the first half of 1946 reveal 29.9 per cent of tuberculosis cases, with this disease as the only cause of death in 16 per cent.

All statistics and publications disclose the striking absolute and relative increase of extrapulmonary tuberculosis and of its death rate. In this increase participate tuberculosis of the glands, the skin, the abdominal organs, eyes, kidneys, bladder and genitals. Isolated exudative pleurisy has likewise increased. The increase in extrapulmonary tuberculosis is less pronounced in children than in those in the age group 15 to 30 and even 30 to 50 years.

The influx into all four zones of Germany of expellees from other countries, such as Poland and Czechoslovakia, complicates statistics and presents many other problems. The tuberculosis rate among the newcomers is often many times as high as among the old stock local population. This is caused by such factors as the complete disruption of their lives, their bad housing, their lack of local connections at their new domiciles, which puts them at a disadvantage with respect to securing food from extralegal sources, and the lack of friendly neighborliness in the new community. Mostly, their health discipline is bad; many of them prefer to hide their sickness rather than to be reported ill. In their unsettled lives they are afraid of new complications, even at the price of foregoing a possibly higher ration card.

Facilities for diagnosis and treatment of tuberculosis are tragically inadequate. X-ray equipment is extremely scarce; tubes, films and chemicals are lacking. The once famous German x-ray industry is greatly reduced. Hospitals which in former times owned four to six machines are now operating with only one or two. All over Germany, there are more cases of tuberculosis than there are available beds for the tubercular. Consequently,

the well and the sick continue to live together. In small villages scarcely one fourth of deaths due to tuberculosis occur in hospitals, in big cities not more than 40 to 60 per cent. The food ration, though higher than the normal one, is far from being satisfactory. The vitamin deficiency is to some extent reflected in the decided seasonal influence on the tuberculosis death rate. The Eastern zone suffers from a serious lack of physicians trained in the field of tuberculosis, especially the extrapulmonary type. Many positions in this field are vacant and hard to fill.

Because of the long waiting time between diagnosis and hospitalization, caused by the lack of beds, several articles in the German medical press have discussed the problem of how to make best use of this period. There are differences of opinion with respect to ambulant pneumothorax and other collapse operations, but all authors stress the necessity of absolute rest in bed, mainly with a view to caloric saving and the poor fuel situation.

Dr. Paul Troch, director of a tuberculosis clinic in Bad Pyrmont, has invented and is testing a new remedy, consisting of a platinum solution and thorium X. Test tube experiments have been successful against the human, bovine and poultry type of tubercle bacilli. Promising animal experiments are also reported. In man, tuberculosis of the joints and bones seems to respond, while with respect to pulmonary cases final judgment cannot as yet be passed.

Danish physicians have come to Germany in order to assist in the introduction of a large scale BCG inoculation program, which has proved successful in their country. Until the present emergency, BCG inoculations were not popular in Germany after a catastrophe which occurred in Lübeck in 1930, when, during the first large scale BCG inoculation program in Germany, 87 of 250 inoculated Lübeck infants died, while only 76 of the others remained well. It turned out later that a fateful error had occurred: virulent cultures had been used instead of the attenuated BCG. The German press used the catastrophe as a pretext to arouse anti-French, nationalistic feelings. Consequently, the Calmette-Guérin inoculation was discredited in Germany. After this long lapse of time, Berlin is now starting a program of large scale BCG inoculations, undertaken on a voluntary basis. The first few hundreds of volunteers will be inoculated this month. After that, wholesale inoculations are planned to be performed in 1948 and 1949. The preferred age groups will be 3 to 6 years and 15 to 20 years. Inoculation material will be provided from Denmark and from Paris.

New Soviet Tuberculosis Law

The Soviets recently passed a new tuberculosis law (Order 297 of the Soviet Military Administration) which organizes the fight against tuberculosis on a zonewide basis. In view of the present inadequate facilities, however, the law is envisaging a goal rather than establishing a workable practice. The whole scope of tuberculosis care will be concentrated in social-medical centers (Fürsorgestellen) which have the following tasks: (1) collection of data on all active cases of tuberculosis; (2) examination and registration of all patients; (3) welfare work; (4) supervision of the working conditions of patients; (5) treatment in the Center; (6) supervision of patients under treatment by private physicians, and (7) hygienic enlightenment. Different from the old Prussian law, not only infectious cases are made subject to registration but all active and suspicious cases, whereby "active" includes all clinical and radiologic indications, aside from simple scars. This procedure is intended to put the tracing of the sources of infections on the largest possible scale. The law calls for preliminary physical examinations and regular roentgen ray check-ups on all food handlers, teachers, doctors, etc. Youths are excluded from tuberculosis hazardous occupations. In individual cases examination, treatment and isolation can be made compulsory. Children may be removed from their surroundings in cases in which their stay there would involve exposure to tuberculosis.

Convention of Internists

Under the chairmanship of Professor Volhardt, Frankfurt, and Professor Siebeck, Heidelberg, the first postwar convention of internists from Southwestern Germany was recently held at Karlsruhe. The main topic for discussion was diseases of the heart, particularly the connection between functional and nervous disturbances and the advances in electrocardiography. Professor Heilmeyer, Freiburg, reported on therapeutic progress during the last few years, with specific reference to sulfonamide drugs and penicillin.

Miscellaneous

Among the 1,800,000 refugees and expellees now living in Bavaria are 1,200 physicians and 300 dentists. The Bavarian Landtag passed a resolution enabling them to practice in the state.

The University of Giessen, the only university in Germany without a medical faculty, has developed plans for the reconstruction of its largely destroyed facilities. As part of this program, the establishment of an independent faculty for nutritional research, patterned after American fashion and attached to the Justus Liebig Hochschule, is planned. This faculty will devote itself largely to the problems of vitamin research.

Professor Lange, dean of the medical faculty of Greifswald (Soviet zone) and director of its Anatomic Institute, and Dr. Dragendorff of the same university were recently arrested for unknown reasons.

The famous pediatrician of Munich University, Professor Meinhard von Pfaundler, died at the aged of 75. He was one of the founders of modern pediatrics and was honorary president of the German Pediatric Society. His widely known "Handbuch der Paediatric" has been translated into many languages.

The Berlin epidemic of poliomyelitis has practically come to an end. All restrictions ordered by the Military Government for the protection of the American community have been lifted as of Nov. 12, 1947.

BRAZIL

(From Our Regular Correspondent)

SÃO PAULO, Dec. 2, 1947.

The Penal Code

Professor Flaminio Favero has commented on and clarified our penal code. He dealt with the clandestine sale of drugs. He made a historical analysis of the trade in poisonous substances, since the code of 1850 up to the present detailed Brazilian legislation, and compared it with Italian jurisprudence (Manzini). For the legal and medical concepts of drugs he gave valuable explanations of international laws on the manufacture and distribution of drugs, to which Brazil has given her support. Professor Favero analyzed the legal regulations in Brazil and, finally, the penal action against the agent, chemist, doctor or dentist. According to Italian law, the act of prescribing noxious substances is aggravated by "the condition of infirmity or the psychic deficiency" of the patient or by his being "given over to the use of drugs." While these were not included in the Brazilian code, they should not fail to constitute an infraction.

Investigation of Paternity

Luiz Silva, professor of legal odontology in the São Paulo Police School, presents in outline the bases for the scientific examination of "heredity likenesses." He comments on methods used before and after Mendel in the investigation of paternity through "hereditary characteristics" and concludes that they have disappeared since the advent of modern legal odontology, which has substituted subjective processes for objective ones, based on the principles of the laws of mathematics applied to biology.

Correspondence

HYPERTENSION

To the Editor:—A wrong impression may be created by the remark in the editorial of November 1 (*THE JOURNAL*, p. 576), that "sodium depletion also has morbidity and even a mortality." Nobody is known to have died from the salt-free treatment of hypertension. The symptomless toleration of a diet which would be rapidly fatal to normal persons is in itself evidence of a vascular abnormality and probably of a need for the diet. The symptoms of sodium deficiency in exceptional cases are too obvious to be overlooked, are quickly and easily corrected and are usually transitory, so that the commonest error will consist in giving too much salt and for too long a time. There is an absolute difference from the mortality and sequels which may follow surgical sympathectomy in spite of care or skill.

Reference is made to the precipitation of uremia by withdrawal of salt in a type of nephritis which is so uncommon that Thorn, Koepf and Clinton (1944) believed their 2 cases to be unique in the literature. As usual, notice has not been taken of the 6 cases of this kind in our series (Allen, F. M., and Sherrill, J. W.: *Treatment of Arterial Hypertension, J. Metabolic Research* 2:429-545 [Oct.] 1922). The treatment by addition of 2 to 10 Gm. of salt is summarized in the tables of this paper, and in greater detail in case 3 of an earlier article in *THE JOURNAL* (Allen, F. M.; Mitchell, J. W., and Sherrill, J. W.: *The Treatment of Combined Diabetes and Nephritis, J. A. M. A.* 75:444-449 [Aug. 14] 1920). Our cases did not reach the collapse stage, which is not adrenocortical deficiency but simple shock, well known to be produced by sodium deficit, whether resulting from traumatic exudation, peritoneal irrigation with distilled water or various other causes. The specific remedy, of course, is administration of sodium salts, as in all shock. The precipitation of uremia in these cases is connected with the loss of concentrating power, so that polyuria is necessary for nitrogen elimination; however, the drinking of water alone causes nausea, and both drinking and diuresis are possible only with a sufficient supply of salt. With a diet as low as feasible in both protein and salt these patients may be kept in fair condition for a few months or years, but the ultimate prognosis is hopeless because of the impossibility of the requisite functional rest.

Various authorities who long denied any effect of salt-free diet have now receded to the position that the benefit is symptomatic and temporary, the judgment in each instance being based on brief inadequate experience. I am still alone in claiming an influence on the disease itself, different from a mere artificial reduction of blood pressure and often evident in long observation even of "refractory" cases showing little or no change in pressure. This contention that the improvement is specific and that progressiveness is arrested was apparently not established convincingly by our large published statistics, because of the variability of cases. However, it may appear significant that in an experience now covering thirty years and several thousand cases I have never seen an essential hypertension patient who on beginning treatment was free from obvious retinitis, angina, uremia or congestive heart failure and who acquired any of these conditions under continued treatment or ever needed mutilating surgery. These results in cases which were mostly rather advanced on beginning treatment should offer hope for reducing the huge mortality due to hypertension by the rational plan which is used in all other diseases, namely, diagnosis and correct treatment at the earliest possible stage. This problem and mortality are important enough to justify placing on record this new issue of accuracy between an individual declaration and the opposition of all the reputed authorities.

FREDERICK M. ALLEN, M.D.
1031 Fifth Avenue, New York 28.

SICKNESS INSURANCE IN AUSTRIA

To the Editor:—I just read an article which appeared in the Austrian edition of the *Austro-American Tribune* of October 1947. (This attacks the American Medical Association for opposing compulsory sickness insurance.—Ed.)

Austria is the classic country of sickness insurance; everybody is insured, even the highest government officials, professors of universities, general directors and, in fact, all those with the highest salaries. As a physician who has practiced for twenty years I have been able to form an opinion about sickness insurance, even though in the beginning I was in favor of such insurance. Permit me to congratulate you that in the United States you do not yet have sickness insurance. I congratulate not only you but also the American people who are gaining by the fact that as yet there is no socialized medicine. Every medical service suffers when it has to be done under restrictions, and this is always the case under government-regulated sickness insurance. If one considers the enormous expenditures for the administrative personnel, the huge buildings that are necessary and, in short, all the complicated machinery that is necessary for the conduct of government-supervised sickness insurance, it can be said that this money would be spent better if it were used to really cure the patients.

Be glad that you can still treat human beings, individuals, that you do not have to collect insurance papers, that you can devote your time to your patients and do not have to waste it keeping records that are needed for the insurance but contribute nothing to the cure of the patient.

Be content to remain, as the article in the *Austro-American Tribune* expressed it, "narrowminded and shortsighted." Use all efforts to retain your freedom and preserve for the American people the good physician.

LUDWIG HERMANN, M.D.

Graz-Kroisbach,
Mariatrosterstrasse 36,
Austria.

Medical Motion Pictures

FILM REVIEW

Peptic Ulcer. 16 mm., color, sound, 1,600 feet (one reel), showing time forty minutes. Prepared in 1942 by the Lahey Clinic, Department of Gastroenterology, Boston. Procurable on loan from: Wyeth Inc., Film Library, 1600 Arch Street, Philadelphia 3.

This film presents peptic ulcer, including the incidence, pathogenesis, diagnosis, treatment, pathology, complications, gastric ulcer and surgery.

It describes in detail the various forms of accepted therapy and the use of the various antacid preparations. It lacks references to the complication, namely, the constipation that sometimes confronts the clinician when antacid is used. The treatment of the various complications of peptic ulcer such as alkalosis is well presented. The hospital management of the ulcer patient may be overemphasized in the film, since at present many gastroenterologists are treating the ulcer patient whenever possible by an ambulatory regimen.

The gross and microscopic pathology is well illustrated.

Although the film is longer than average, it gives a complete and rapid review of the facts about peptic ulcer and is essentially accurate in detail. Various methods of visual presentation including animation, charts, graphs, drawings, radiographs and photomicrographs are used to excellent advantage in this film.

This film is suitable for showing before members of medical societies, senior medical students, residents and general practitioners.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Hospitals, for Profit: Burns—Application of Doctrine of Res Ipsa Loquitur.—The plaintiff sued for damages for burns suffered by her at the time she was born, the burns having been the result of the alleged negligence of the defendant hospital. From a judgment in favor of the plaintiff, the hospital appealed to the Supreme Court of Appeals of Virginia.

The plaintiff's mother was admitted to the defendant hospital March 14, 1942, and the plaintiff was born during the night of March 17. It was a hard birth, but the plaintiff was normal and without any injuries. The next day the physician who performed the delivery was told by the nursery nurse that the baby had a blister. On examination he found a burn on the baby's thigh about as big as a silver dollar, which in his opinion was caused by a hot water bottle. He said that it was a very common practice in a hospital to wrap up one or two hot water bottles and put them on either side of the baby to get the proper heat; if that was done in a proper way there would be no burn. On cross examination the physician stated that at birth the baby had a blue tinge and very likely had been given oxygen and that this baby could have been put in a resuscitator bassinet for that purpose. He stated that he was in the delivery room until the plaintiff's mother was moved to her room, which was not more than half an hour from the time of the delivery. It was possible, he said, for the baby to have been in the bassinet for that period and then to have been taken immediately by the nurse to the nursery without any order from him. He did not consider it reasonably possible that the blister could have been caused several hours before he examined it in the nursery the next morning, and he did not see how it was possible for the burn to have been received in the resuscitator bassinet. It did not seem reasonable that a burn from the bassinet would be limited to just one spot; all the time that it had been used he had never heard of a baby's being burned; and "with at least four people in that small delivery room, with a baby that we thought necessary to look after enough to put it there, I don't think it could possibly be put on that iron grill without us knowing something about it; and I also think that if it was blistered we would see it—not the next morning." The plaintiff's mother was not told about the burn until a week later, just before she went home from the hospital. The superintendent, Mrs. Stein, then told her that she did not know how it happened, whether it came from hot water bottles or not, but that it happened in the nursery on the morning after the child was born. She said she was notified of the accident by a nurse—she did not know which one—late in the morning after the baby was born; that she made an investigation but never did find out how the child was burned; that she remembered three nurses who were on night duty then but did not remember which one was in charge of the delivery room. She questioned the nurses, and they said that they did not know how the accident happened; any one of the three could have put the hot water bottle with the baby, but she did not know which one took charge of the baby, and they did not admit to her which one did.

The hospital's chief contention on appeal was in relation to an instruction given by the trial court, which gave the plaintiff the benefit of the doctrine of *res ipsa loquitur*. A private hospital, said the court, owes to its patients such reasonable care and attention for their safety as their mental and physical condition, if known, may require. The care to be exercised should be commensurate with the known inability of the patient to take care of himself. In a proper case, the court continued, a plaintiff may be aided in establishing a breach of such duty by a legal inference of negligence from proved facts. He may show a situation to which the *res ipsa loquitur* doctrine applies. Generally speaking, that doctrine applies in negligence cases where the instrumentality which caused an injury is within the exclusive possession and control of the person charged with negli-

gence, and where such person has, or should have, exclusive knowledge of the way that instrumentality was used, and where the injury would not ordinarily have occurred if it had been properly used. We have, the court pointed out, held that the doctrine was not to be applied in malpractice cases primarily because as a matter of common experience and knowledge a bad result affords no presumption of negligence. The physician or surgeon does not warrant a cure, and an unfavorable result may be, and often is, attributable to one or more factors for which he is not responsible and may happen notwithstanding the exercise of a very high degree of care and skill. On the other hand, the court said, there is no good reason why the application of the rule should be limited to cases involving a particular activity, such as cases of injury to railroad passengers by derailment. Referring to a California case in which the patient alleged that she was burned on the legs by a hot water bottle while she was unconscious from an anesthetic, the court quoted: "The doctrine *res ipsa loquitur* is properly applied to the facts of this case. The patient was unconscious. Under its contract with her the defendant corporation owed her a duty of protection, which was violated by the use of an instrumentality which produced the painful results which were made manifest when she came out from the influence of the anesthetic. Proof of the accident carried with it the presumption of negligence." And in another California case it was said: "Plaintiff was rendered unconscious for the purpose of undergoing surgical treatment by the defendants; it is manifestly unreasonable for them to insist that he identify any one of them as the person who did the alleged negligent act."

On the evidence produced in this court, the court of appeals said, the accident would not have happened but for the negligence of the defendant's employees. It resulted from the use of instrumentalities under the control of the defendant and to a helpless patient also in the possession and under the exclusive control of the defendant. Plaintiff was powerless to ascertain why and how it happened. If it happened without the negligence of anybody, contrary to ordinary experience, the defendant could have presented evidence so to indicate or establish. None was produced, and it was proper to tell the jury that an inference existed in favor of the plaintiff in the absence of any explanation by the defendant.

Accordingly the Supreme Court of Appeals held that the trial court's instruction with reference to the doctrine of *res ipsa loquitur* was proper and that the judgment in favor of the plaintiff should be affirmed.—*Danville Community Hospital, Inc. v. Thompson*, 43 S. E. (2d) 882 (Va., 1947).

Paternity: Rh Factor in Cases of Questioned Parenthood.—This case, involving the paternity of a child born some ten or eleven weeks after the parties hereto were married, was heard in the domestic relations court of the City of New York, family court, Kings County, New York.

The presumption of legitimacy, said the court, of a child born in wedlock is as strong as any known to the law, but it may be overcome by competent and convincing proof. Under the Lord Mansfield Rule the illegitimacy of a child could not be testified to by his parents. In the absence of testimony bearing directly on the paternity of the child, the court would not be authorized to make a finding contrary to and in contravention of the Lord Mansfield Rule. There is, however, said the court, testimony bearing directly on the question as to whether or not the respondent herein is the father of the child. The parties and the child submitted to blood-grouping tests. It would appear that under two recognized blood-grouping tests the blood of the parties, including the child, was compatible. Compatibility of blood does not *ipso facto* determine paternity. When the blood of the parties and the child is incompatible the alleged father, by reason of such incompatibility, may be excluded.

The respondent contends that, despite the compatibility of the blood under the A-B and M-N blood-grouping tests, he is not the father of the child. Extensive testimony was given by Dr. Alexander S. Wiener. The conclusion reached by Dr. Wiener, as the result of the Rh or Hr test, was that the respondent herein is not the father of the child, and his conclusion was definite. His testimony on that score remains unchallenged.

Dr. Wiener testified: "There are two kinds of Rh and two kinds of Hr, and by studying these cases we were able to obtain serums from them which we can use to identify these various Rh and Hr's." Further on in his testimony the physician stated, in answer to a question by the court: "If you visualize a red cell as a bag containing the hemoglobin, the outside envelope has to have a structure, and that structure is like a patchwork, like a crazy quilt, a patch here, a patch there. Now these patches we cannot chemically identify, but apparently each has a separate structure so that a special serum will hook on to the patch and clump it. Now one type of patch determines the A and B; a different kind of patch determines the M and N, and the third type of patch determines the Rh and Hr." It is evident that the determination of the type of blood is fixed by the serums used. Nowhere, said the court, is there a judicial determination anent the Rh blood-grouping test. However, the medical fraternity has in no uncertain terms expressed itself in an editorial published in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* (125:495 [June 17] 1944) as follows:

In view of these family data, as well as the results obtained in the study of mother-child combinations and the statistical analysis of data on the distribution of the Rh blood types, the theory of six allelic genes appears to be firmly established. Therefore, the medico-legal application of the Rh blood types in cases of disputed parentage is justified, provided suitable potent reagents are available. The use of the Rh tests in such cases, with the A-B-O groups and M-N types, raises the chances of excluding parentage from about 33 per cent to almost 45 per cent.

Dr. Wiener's testimony and his conclusions, evidently arrived at since 1944, are that 55 per cent are definitely excluded under the Rh blood grouping tests. Cross examination of Dr. Wiener did not in any wise change his conclusions. No testimony was admitted by the petitioner in an effort to impeach the doctor's credibility or his ability and standing as a physician or to negate his conclusion. The courts cannot without basis discard the testimony of a reputable and competent witness who has testified under oath.

Under section 126-a of the domestic relations law and section 34 of the domestic relations court act, testimony on blood tests is admissible in evidence, and such testimony is to be given the same consideration as any other type of testimony. If such testimony is believable, the court cannot reject it. In this case, as in every other instance, evidence must control. Whatever the sentiments of the court may be, it cannot make compromise with what the facts dictate. The proceeding must be determined on the testimony adduced and the facts established. On the testimony and on the facts established, concluded the court, I must find that respondent is not the father of the child.—*Saks v. Saks*, 71 N. Y. S. (2d) 797 (N. Y., 1947).

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARD OF MEDICAL EXAMINERS BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in *THE JOURNAL* Jan. 10, page 130.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I & II*. Various centers, June 21-23. *Part II*. Various centers, April 26-27. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Oral*. New York, April 12-15. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 22.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Oral*. Philadelphia, April 2-4. Final date for filing application is January 19. *Written*. Group B. Various centers, Feb. 16. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral*. San Francisco, April. Chicago, June. Final date for filing application is Feb. 1. *Written*. Oct. 18. Final date for filing application is June 1. Asst. Sec.-Treas., Dr. W. A. Werrell, 1 West Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral*. Chicago, May or June. Final date for filing application is Feb. 1. Sec., Dr. W. J. German, 310 Cedar St., New Haven, Conn.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral*. Baltimore, May. Chicago, Oct. Sec., Dr. S. Judd Beach, 56 Ivie Road, Cape Cottage, Me.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral*. Chicago, June 16-19. Final date for filing application is Feb. 1. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City.

AMERICAN BOARD OF PATHOLOGY: Philadelphia, March 8-10. Final date for filing application is March 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis, Mo.

AMERICAN BOARD OF PLASTIC SURGERY: Examinations are given in April and November of each year in the home town of applicants. Sec., Dr. Robert H. Ivy, 1930 Chestnut St., Philadelphia.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: *Oral*. Washington, D. C., May 13-15, 1948. Final date for filing application is Feb. 15. Sec., Dr. F. J. Bracecland, 102-110 Second Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF RADIOLOGY: *Oral*. Chicago, June 1948. Final date for filing application is March 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

Miscellany

MEDICAL SUBJECT HEADINGS

Under the auspices of the Army Medical Library a two day symposium on Medical Subject Headings was held in Washington, D. C., Dec. 12 and 13, 1947. The symposium was built about two objectives, to explore the approaches used by medical indexers and medical librarians to the related problems of printed bibliographies and card catalogs, and to determine principles which might be acceptable to both groups in their selection of new medical terminology for bibliographic purposes.

The participating members included Magdalene Freyder, American Medical Association; Murrell C. Wellman, American Dental Association; Eileen R. Cunningham, Medical Library Association; Estelle Brodman, Columbia University Medical Library; Dr. Claudius F. Mayer, Army Medical Library; Irene M. Strieby, Lilly Research Laboratories; Janet Doe, New York Academy of Medicine; Dr. Sanford V. Larkey, Welch Medical Library; D. J. Haykin, Mortimer Taube, Sarah G. Mayer, C. W. Gull, Morris C. Leikind and Leo E. La Montagne of the Library of Congress; Mabel McLaughlin and Miriam M. Wilson of the Veterans Administration; Dr. Helen W. Kaan, Dr. D. L. Ballard and Michael J. Filippi of the National Research Council; Ruth Griffin and Ruth E. Rodier, Naval Medical Center; Clara Manson, College of Physicians of Philadelphia; Mary Louise Beitzell, Social Security Administration; Dorothy M. Cramer, National Institute of Health; Dr. Thelma B. Dunn, National Cancer Institute; Margaret C. Schindler, Department of Agriculture; Wyllis E. Wright, Williams College, and representatives of the Army Medical Library.

Following the reading of papers, discussion developed around the following themes:

1. The problem of adapting medical subject headings to a changing nomenclature. Although the core of medical terminology, as represented by adopted headings in a printed list or card catalog, is relatively stable, day to day use in international medical literature constantly establishes new terms. Subject headings used for periodical literature are particularly susceptible to such change.

2. The lack of a standard list of subject headings for the medical sciences. Catalogers and indexers must borrow from whatever source they can find. The participants in the symposium passed a resolution urging the creation of such a standard list.

3. Direct or indirect headings, involving the extent of alphabetical classification desirable in a list of subject headings. Reconsideration of classed catalogs was suggested by several participants. The general principle of direct (nonclassified) headings, as well as that of specificity, was reaffirmed.

The symposium was concluded by the adoption of a list of principles to be used in the selection of subject headings for medical literature.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Methylthiouracil in Thyrotoxicosis.—Barfred treated 61 patients with thyrotoxicosis, 51 women and 10 men between the ages of 18 and 72 years, with 4-methyl-2-thiouracil. Eighteen patients were given large doses of methylthiouracil. The average dose was 1.2 Gm. daily. The drug had to be discontinued in 8 instances, and it caused reactions in 14 patients. A smaller average dose of 0.57 Gm. was given to 43 patients. In this group the drug had to be discontinued in 5 instances; reactions were caused in 20 patients. Agranulocytosis occurred in 1 of these latter patients who had recovered. The largest single dose recommended is 0.4 Gm. daily. If this does not give any results for the first seven or eight weeks, it is justifiable to wait two or three weeks more for a drop in the basal metabolic rate. In 44 of the 61 patients it was possible to complete the treatment. They were fully capable of work in an average of 1.2 months after treatment was started. Sustained remission with an average observation period of seven and one half months occurred in 16 patients after treatment of approximately five months' duration. The sustained remissions occurred most frequently in patients with a small to moderate sized goiter in the young and middle-aged groups, especially in men, and in cases in which the disease had not been of long duration. The complications and the severity seemed to have no significant influence on the ultimate result of the treatment. Four patients were failures. In 18 iodine-resistant patients treated with methylthiouracil the basal metabolic rate fell much more slowly than usual. The common incidence of a positive urobilin test in association with other untoward reactions suggests that this test represents a toxic manifestation; the addition of this simple check-up is recommended. Methylthiouracil is ineffective in cases of increased basal metabolic rate caused by acromegaly. Methylthiouracil seems to be more effective than thiouracil and about as effective as propylthiouracil.

Lumbodorsal Splanchnicectomy.—Freis and Smithwick made repeated blood and "available fluid" determinations on a series of 10 patients, 8 men and 2 women between the ages of

21 and 45 with essential hypertension, for periods up to six months following lumbodorsal splanchnicectomy. The "available fluid" volume expresses the total volume in which a 5 per cent solution of sodium thiocyanate is distributed, including the plasma volume, the amount that enters the red cell and its distribution in the extracellular space. The total blood volume was reduced in 9 cases in the period of eight days to two weeks following surgical intervention, due primarily to a diminution in red cell volume. Despite a continued reduction of blood pressure the total blood volume was restored to the approximate preoperative level at the end of six months following the operation. A slight reduction of the hematocrit value persisted, the deficiency being made up by a compensatory increase in plasma volume. Coincident with the reduction in blood volume noted in the second postoperative week there was an increase in "available fluid" volume. This increased value was restored to the preoperative level over a period of several months. Previous observations that the total blood volume is within normal limits in patients with essential hypertension were confirmed. In relation to surface area the "available fluid" volume of patients with hypertension was also observed to be within the normal range. It is suggested that the reduction in blood pressure following sympathectomy is not dependent on changes in total blood or "available fluid" volume.

Antireticular Cytotoxic Serum in Arthritis.—Rogoff and his co-workers produced arthritis in rats by the injection of pleuropneumonia-like organisms. One group of animals served as untreated controls. Of a second group some rats were injected with normal rabbit serum, while the test animals received patent homologous antirat antireticular cytotoxic serum (ACS) before inoculation with the organisms. A third group of rats received injections of ACS simultaneously with the inoculation of pleuropneumonia-like organisms and repeated serum injections on the third and sixth day. The polyarthritis induced in rats by the inoculations was not affected in time of onset or severity by the use of the antireticular cytotoxic serum either prophylactically or therapeutically. Twenty-nine patients with rheumatoid arthritis were given subcutaneous injections of ACS at intervals of three or four days. The doses varied originally from 0.5 to 1.5 cc. and were reduced later to 0.3, 0.6 and 0.9 or 1 cc. After intervals of four to six weeks many patients received a second series of injections, some a third and several a fourth series. Fourteen patients were injected with normal rabbit serum having no antireticular cytotoxic activity. Three patients who received ACS showed symptomatic improvement and 3 showed objective improvement; in 16 there was no change and 7 became worse. Of the control group 1 patient improved symptomatically, 2 objectively, 7 revealed no change and 4 became worse. ACS treatment was of no benefit in the great majority of patients with rheumatoid arthritis. In the few patients who experienced improvement it was only temporary. There was no dependable effect of the antireticular cytotoxic serum on the clinical course of rheumatoid arthritis.

Bilateral Ophthalmoplegia in Poliomyelitis.—Wright reports the history of a woman, aged 24, who entered the hospital on September 18, 1946, complaining of dizziness, diplopia, vicelike headache and nausea. Slight nausea and dizziness had

been present for five days prior to admission, but diplopia occurred on the day of admission. Six days later there was noted bilateral ptosis and weakness of the muscles of the back and of the extremities. Two weeks after the onset ophthalmoplegia was complete in both eyes. A left seventh nerve paralysis had developed, which resulted in inability to close the left eye. Voiding had also become difficult. The lesion of the facial nerve then slowly regressed. Eight weeks after onset, the pupils had returned to normal and accommodation was sufficient to read 8 point type at 13 inches unaided. Convergence remained nil. A severe weakness of all muscles of both hands remained. Six months later the right medial rectus was functioning; the left medial rectus was paretic, and scarcely any motion had returned to the vertical muscles. Convergence was nil and the wrist and foot drop remained severe. Diplopia was an early symptom in this patient, and extraocular muscular involvement was prominent well in advance of spinal cord symptoms.

Pulmonary Edema and Eosinophilia.—Henderson and Peirce report 1 case of transitory shifting pulmonary shadows associated with pronounced fluctuating blood eosinophilia (Löfller's syndrome) in an allergic man aged 42. The patient's personal and family history bore evidence to his allergic predisposition. In addition to house dust and ragweed pollen, the patient also exhibited evidence of bacterial allergy to the infect-

ing organism, *Hemophilus influenzae*, which was observed constantly in the sputum and in infected sinuses. At a later period, on readministration of the specific vaccine, there developed joint and muscle pains, fever and pronounced purpura of the Schönlein type, and during this episode a transitory bundle branch lesion was revealed by the electrocardiogram. This indisputable evidence of vascular allergy is corroborative of the view that the Löfller shadows are due to allergic edema of the interalveolar pulmonary tissue with its widespread capillary connections.

Fibrous Dysplasia of Bone.—Bogart and Immler report 4 cases of fibrous dysplasia of bone confirmed by biopsy in 3 young men between the ages of 18 and 29 and in a boy aged 12 years. The ischium, the tibia and the fourth rib on the right side were involved in the first, second and third cases, respectively, and both the tibia and the femur were involved in the fourth case. Attention is directed to the fairly frequent occurrence of lesions involving one or a few bones, in which the symptoms are comparatively mild. Involvement of bones is apt to be on one side of the body but may be on both sides. Although the etiology is unknown, the condition is thought by most authors to represent an anomalous skeletal developmental defect. It usually starts in childhood and develops slowly, often being recognized only during adult life. The osseous changes demonstrated on roentgenographic examination are suggestive and in some cases are diagnostic. The final diagnosis is best made after careful consideration of the roentgen and clinical observations and correlation of these observations with the biopsy. Extraskelatal changes occur as a rule only when the bone changes are well defined. While pigmentation of the skin occurs in men, it is apt to be more pronounced in women. The precocious sexual development and premature skeletal growth and maturation seem to occur only in women. Hyperthyroidism may occur in either sex. The disease is slowly progressive but may reach a static stage in adult life. Life expectancy is not influenced. A curative type of therapy is not known. Elective surgical procedures should usually be avoided, as new bone is laid down slowly and frequently does not develop.

Radium Needles in Cancer of Bladder.—Lenz and his co-workers treated 44 patients with microscopically proved cancer of the urinary bladder in or near the trigone by suprapubic cystostomy and implantation of radium needles during the period 1931 to 1941. After exposure of the tumor by cystostomy, the first row of needles was inserted into the muscularis, under the tumor from above down toward the neck of the bladder, including 2 or 3 cm. peripheral to the tumor, depending on its size and invasiveness. Additional needles may be placed at right angles to and across the nonradiating points and eyes of the first row in order to raise the low radiation intensity in these areas. A tumor dose of 8,000 gamma roentgens seems preferable to smaller doses. Thirty-four patients died of persisting or recurring cancer, and 1 died fifteen years after treatment, cancer not being demonstrated on necropsy. Nine patients are living and appear to be free from clinical evidence of cancer. Prognosis is poor if the cancer has extended through the wall of the bladder and if the ureters are involved. Results were best in small papillary tumors, though some of the larger infiltrating cancers responded well to the treatment.

Primary Atypical Pneumonia.—The study by Reich and his associates is based on an analysis of 440 consecutive cases of primary atypical pneumonia, which occurred between June 1943 and June 1946. Most of the cases occurred during the first

eight weeks of the patients' military service. Factors involved were: increased exposure to the elements; overexertion; tension and worry; interference with sleep due to change of hours and various duty details, and readjustment of body habits, resulting in states such as constipation. Of considerable importance was the influence of droplet infection due to sleeping, eating and attending class in close proximity to others. A definite prodromal stage averaging about four days was found to occur. The prodrome is most frequently mistaken for an infection of the upper part of the respiratory tract. Serial roentgenographic studies are a great help in arriving at an early diagnosis and in following the clinical course, because the prodrome is ill defined, the physical signs are variable and the laboratory methods give nonspecific results. Specific therapy is unnecessary unless the patient is dangerously ill. The sulfonamide drugs or penicillin is indicated in cases that reveal evidences of progressive or massive pulmonary involvement, suggestive or proved presence of secondary invaders or signs of severe toxemia, dyspnea and cyanosis. Penicillin is slightly more effective and is accompanied by fewer reactions than are the sulfonamide compounds. Transfusions of whole blood from patients convalescing from primary atypical pneumonia are of great value in supplying antibodies of high titer in dangerously ill patients.

Bell's Palsy.—Kettel operated on 50 patients with Bell's palsy by the method of Ballance and Ducl. In 11 of the 50 patients there was necrosis of the mastoid cells; in 5 of these patients necrosis spread to the entire cellular system, whereas in 6 patients it was observed only in the apex of the mastoid process and particularly around the stylomastoid foramen. In 18 patients the fallopian canal was macroscopically soft and could be opened in a few minutes; in the rest of the patients it was hard like ivory. In 28 patients the nerve was unquestionably edematous macroscopically; in 2, possibly atrophic, and in 1 the changes were so violent that the continuity of the nerve was completely interrupted. It is suggested that Bell's palsy is a primary ischemic paresis of vascular determination. Decompression was carried out in 25 patients in whom signs of returning mobility had not appeared after an observation period of two months. In none of 20 of these patients could the paresis be noted when the face was at rest. They could close the eye completely, smile and laugh, but to a varying degree; only 2 patients had recovered completely. Decompression was carried out in 17 patients in whom the spontaneous recovery of mobility had ceased before complete restitution had been obtained. Thirteen of these were ready for reexamination; in 9 patients surgical intervention had brought about an improvement of mobility, and 1 of these had recovered completely. One of the patients had suffered from a distinct contracture, which disappeared immediately after the operation. Two and one half years afterward there had been no relapse. At a later date the same observation was made in 2 more cases. This shows that the contracture is released by reflex and is due to an irritation of the facial nerve in the fallopian canal. Eight patients had had recurrences of facial palsy from two to nine times. None of them had a relapse after the operation; the mobility improved

in every instance, and 2 patients recovered completely. The favorable effect of the decompression is due to the fact that on exposure of the nerve the circulation of the blood is in some way improved by release of the pressure on the vasa nervorum proper or by the establishment of collateral circulation.

Double-Lumened Plastic Tube for Intestinal Intubation. W. H. Honor and H. M. Smathers.—p. 498.

Total Gastrectomy.—According to Pack and his associates removal of the stomach is the ideal operation for gastric cancer. Total gastrectomy is both an excision of the entire stomach and dissection en masse of the related lymph nodes. The authors review observations on 41 patients who underwent total gastrectomy. Thirty-seven stomachs were resected for carcinoma, and 1 for an extensive reticulum cell sarcoma. Of the 3 lesions which proved to be benign, 1 was noncancerous linitis plastica, probably due to syphilis, and 2 were large benign ulcers high on the lesser curvature. A significant factor may overshadow the advantage of maintaining protein balance with an orojejunal Levine tube. In the 16 cases in which a jejunostomy was performed there were 4 operative deaths, only 1 of which was due directly to a pulmonary complication, while among the 25 patients who had feedings by Levine tube there were 5 deaths. The irritation from a foreign body in the nose and throat may cause considerable nasopharyngeal secretion, and with the splinting of the pharynx possibly depressing the cough reflex, pulmonary complications may be invited. The tube may be withdrawn earlier than ten days with reliance on a less nourishing routine. There were 13 operative deaths, a mortality rate of 31.7 per cent. Seventeen patients survived an average of eighteen months; 8 of the 17, who were without nodal involvement at the time of operation, averaged twenty-six and three-tenths months. Of the 11 patients still living on Dec. 1, 1945, 1 has evidence of recurrence of his cancer. Seven patients who had resection for carcinoma have no evidence of recurrence, and 3 who had the operation for benign lesions are asymptomatic. In the series for cancer, there are 5 patients who survived more than three years. None of these gave evidence of extension of the cancer to tributary lymph nodes at the time of operation.

Decortication in Chronic Empyema.—Curreri and Gale point out that in chronic empyema the deposition of fibrous tissue on the pleural surfaces results in an immobile, unyielding and nonexpansile lung. Delorme advocated in 1894 decortication of the binding scar from the visceral pleura, but surgical knowledge was insufficiently advanced at the time to execute this procedure successfully. In World War II Churchill and his thoracic teams in the European theater were confronted with numerous hemothoraxes and pyohemothoraxes with nonexpansile lung. Thoracoplasty in these otherwise normal persons would most certainly lead to permanent semi-invalidism. They met this challenge by reconsidering Delorme's decortication. Well trained thoracic surgical teams, use of antibiotics and blood transfusions resulted in a low mortality and a minimum of complications. The number of cures was remarkably high. The optimum time for surgery is within six weeks following the injury. The authors report 2 cases of chronic pleuritis successfully treated by decortication. It is important to know the extent of pathologic change in the underlying pulmonary tissue and bronchi. If both lobes of the lung are involved, decortication is useless unless it is followed by immediate complete thoracoplasty. In the presence of tuberculous bronchitis or stenosis, reexpansion by decortication may reactivate the disease or may

produce shifting of the mediastinum with overexpansion of the contralateral lung. The authors believe that decortication for tuberculous empyema with nonexpansile lung should be reserved for those cases of disease limited to the upper lobe and without evidence of tuberculous bronchitis.

 Hazards of Butchering. J. M. Palm.—p. 1154.

Hazards of Home Butchering.—Palm shows that due to the increased number of frozen food lockers and the increase of home processing of meats the hazards involved in home butchering are also increasing. In the past year the author has observed 5 cases of tularemia, 3 cases of brucellosis and 2 cases of erysipeloid infection. The cases of tularemia were all of the ulceroglandular type. Two patients were brothers who had helped to butcher the same hogs. The livers of the hogs were considered unfit for consumption, as a result of "spotting and mottling," and were discarded. Many hogs are infected with tularemia, because they graze in the field and may feed on an infected rabbit or other animal which may have died of the disease. The 3 cases of brucellosis came from the processing of infected beef. The 2 cases of erysipeloid infection occurred in 2 persons who were neighbors and had assisted one another in their "fall butchering."

Effects from Repeated Blackouts.—According to Wood and his associates, it is an established fact that the loss of vision and consciousness which may result from exposure to positive acceleration in aircraft or on the human centrifuge are caused by stagnant anoxia of the retinas and brain. During the war in the effort to develop and perfect antiblackout devices, many of the personnel of human centrifuge laboratories served

repeatedly as subjects in tests of this equipment. Such tests involved repeated exposures to high positive accelerations and consequently a considerable number of blackouts and episodes of unconsciousness. Since accurate physiologic recordings were taken during these tests, information is available as to the number and duration of the symptoms of these persons. The present report deals with data which have been collected on 4 of the personnel of the Mayo centrifuge laboratories who have undergone the greatest number of exposures to acceleration. From these data it can be concluded that, at least from the point of view of permanent residual dysfunction, the human brain is relatively resistant to repeated five to ten second periods of stagnant anoxia. Inasmuch as nearly five years have elapsed since these men began these exposures to acceleration and one and one half years since the exposures were concluded, it seems highly probable that untoward effects will not develop. The number of the blackouts experienced by the persons included in this report is considerably greater than those experienced by pilots. Consequently, the average pilot has little or nothing to fear in regard to the development of residual or permanent effects as a result of the blackouts or episodes of unconsciousness that he may experience in flight.

Diuretic Factor in Urine.—Little says that the possibility that some urinary diuretic factor does exist has been tested by the infusion of canine and human urine and dialyzed human urine into normal unanesthetized dogs. When the rate of urinary flow and total volume of urine excreted were compared with the rate and volume obtained following the injection of an appropriate control solution, it was found that a considerable diuresis resulted and that it could be attributed to the presence of some diuretic factor in the urine or dialyzed urine.

Toxicity of Antimalarial Agents when Employed Jointly.—In the treatment of malaria quinacrine, quinine and pamaquine have been employed jointly with the supposition that a combination of these may be more effective than the individual drugs. Chen and Geiling investigated by means of intraperitoneal injection in mice the acute lethal toxicities of quinacrine and quinine, quinine and hydroxyethylapocupreine, quinacrine and pamaquine, quinine and pamaquine, quinine and pentaquine. It was found that the combinations of these antimalarials are different in their joint toxicity: (1) quinacrine and quinine, quinine and hydroxyethylapocupreine act independently and similarly (2) quinacrine in sublethal doses and pamaquine act independently but diversely. (3) Quinine and pamaquine, quinine and pentaquine are synergistic in their joint action.

Treatment of Motion Sickness.—Monto believes that the incidence of motion sickness in modern methods of travel is sufficient to warrant serious consideration both as to prophylaxis and treatment. Scopolamine hydrobromide has been found to be the most effective anti-motion sickness medicament. When this drug is combined with acetylsalicylic acid in a chewing gum base, the resultant combination affords a most satisfactory therapeutic agent in prophylaxis and treatment of motion sickness.

Peritoneal Irrigation of Uremia.—For the treatment of uremia, Connolly and Lempka used continuous intraperitoneal irrigation and continuous gastric lavage with a twofold purpose in mind: first, to prevent azotemia from reaching a degree that would cause death before the kidneys could function again, and second, to reduce the azotemia to a point where reparative processes could be carried on at a faster pace, thereby allowing the kidney to resume function at an earlier date. The authors present the histories of 2 patients, who were treated with intraperitoneal irrigation. The treatment is not without danger. Peritonitis is possible, but it is avoidable with the use of bacterial filters and antibiotics. The likelihood of peritonitis is reduced by putting drainage tubes in properly the first time and avoiding repeated reinsertion. Another danger is pulmonary edema due to forced intravenous fluids and peritoneal irrigation with improperly composed fluids. With no urinary output, 1,000 cc. of fluids, given intravenously each day, is considered sufficient. The optimum time to start intraperitoneal irrigation has not been determined, but it seems to be of no advantage before uremia has developed, and it should be discontinued as soon as the kidney is able to resume function.

Methemoglobinemia in Infants from Nitrates in Water.—Stafford says that methemoglobinemia in infants who have ingested well water containing a high concentration of nitrates has been reported in Iowa, in Kansas and in Belgium. One proved case and 1 presumptive case, which were observed in Nebraska, are reported in this paper. One of the infants became severely ill on a formula of powdered milk when she had not been cyanosed on a formula of evaporated milk, which used less water from the farm well. Perhaps the diarrhea and slow gain in weight were symptoms of nitrate toxicity. It is possible that the inflamed mucosa of her intestine allowed more rapid absorption of the nitrates formed from the ingested nitrates. In most of the reported cases there has been an associated gastrointes-

tinal disturbance. Methylene blue placed in the stomach by tube in proper dosage rapidly relieves methemoglobinemia. Ascorbic acid is also effective against methemoglobinemia, but the action requires several hours. Thiamine is apparently as effective as methylene blue and is not toxic, but it is not readily available. Niacin is also effective. Spontaneous recovery from methemoglobinemia occurs in about four days if the source of the nitrate is removed. This apparently occurred in the second patient during her first readmission to the hospital. It is believed, however, that the first case would have terminated fatally if the infant had not been actively treated. The author stresses that formula-fed infants should not be dismissed to rural areas in which the nitrate content of the water is not known to be safe.

- Diffuse Fibrosis of Myocardium.—p. 593.

Malignant Neoplasms of Thyroid.—Rogers and his associates point out that the value of extirpating goiters, particularly nodular ones, for the prevention of cancerous neoplasms of the thyroid has been the subject of considerable discussion. They reviewed the records of patients with goiter admitted to the Boston City Hospital, the Johns Hopkins Hospital and the Massachusetts General Hospital. A diagnosis of cancer was made in 64 cases, or in 1.99 per cent of all the patients with goiter. Ten additional cases of cancer, not proved histologically, would bring the incidence to 2.29 per cent. The majority of patients who died of cancer of the thyroid or had widespread extension had tumors that were classed as highly malignant. These were usually characterized by the sudden appearance of a mass in the neck, although at times they arose in a previous goiter, and they pursued a rapidly fatal course. Such tumors are seldom removed completely by prophylactic surgery. In cases classed as tumors of moderate or low grade cancer there were few deaths (none in the latter), and the results of treatment were fairly satisfactory. When one considers that even after the removal of a benign tumor of the thyroid or a clinically unsuspected cancer development or recurrence of a malignant neoplasm is not infrequent, the value of routine prophylactic surgery on all nodular thyroid glands becomes less impressive. Moreover, operations on nontoxic goiters are associated with complications and are sometimes fatal. Single nodules, particularly in young persons, should in most cases be removed, and in the absence of thyrotoxicosis any nodule showing an increase in size, in firmness or in fixation should be extirpated. Single nodules or masses in the thyroid are the most frequent site of malignant lesions.

Penicillin in Treatment of Carriers of Streptococci.—Goerner and her associates say that penicillin has been administered to patients found to have positive throat cultures with the view to preventing the spread of hemolytic streptococci from one patient to another. Eighteen chronic carriers of beta hemolytic streptococci and 2 of acute streptococcal tonsillitis were each treated with a total of 1,200,000 units of penicillin, given intramuscularly during ten days. In 17 cases the infecting organisms were eliminated permanently from the throat cultures. One group A streptococcus and two that did not belong to group A, C or H failed to disappear. In 5 cases in which tonsillectomies were performed, the tonsillar fossae and sectioned tonsils were free from hemolytic streptococci one hundred and twenty-five to one hundred and eighty-five days after treatment. In 2 cases the antistreptolysin O titers did not rise after acute streptococcal infections that were promptly treated with penicillin. Injections of penicillin given in slowly absorbable form once a day for ten days were observed to be successful in eliminating the beta hemolytic streptococcus carrier state in 5 of 6 cases. The ability to eliminate beta hemolytic streptococci

from the throats of most patients in close contact with persons who have had rheumatic fever suggests a practical method of protecting the latter group from infection due to the beta hemolytic streptococcus. Further observations are needed to ascertain whether prompt penicillin therapy for acute infections due to hemolytic streptococcus in subjects with rheumatic fever may decrease the likelihood of a recurrence of rheumatic fever.

Decubitus Ulcers in Paraplegics.—On the basis of observations in over 50 cases of decubitus ulcers in paraplegic patients Kostrubala and Greeley believe that the following details are essential to arrive at uniformly acceptable end results: 1. All patients are given large amounts of penicillin before and after operation. In addition, succinylsulfathiazole is used when closure of the ischial decubitus ulcers is undertaken. 2. The ulcer is excised, including the pyogenic membrane, well beyond the ulcer borders into apparently healthy skin and subcutaneous tissue. 3. All underlying bony prominences are removed. 4. The bony stump is covered with a flap of adjacent fascia, or fascia and muscle, in the ischial lesions to prevent adherence to the overlying skin flap and to aid in filling the dead space. The exposed cancellous bone helps to supply increased vascularity to the transposed overlying soft tissues. 5. All cutaneous defects are repaired with large rotated border flaps of skin and subcutaneous fat. No attempt is made to suture the donor area, since avoidance of tension is of prime importance. The donor area is covered with a split thickness skin graft. 6. The flap and graft are covered with a large and bulky dressing applied under moderate pressure. In decubitus ulcers which have been closed by following the foregoing principles there have not been recurrences of ulcers in the rotated skin flaps. It is believed that amputation of the bony prominences is most important in the prevention of recurrences.

Medical Treatment of Peptic Ulcer.—Kahrs and Schrumpt present a follow-up study of 239 cases of gastric and duodenal ulcer treated during the period 1938 to 1942. Seventeen patients died during the observation period and 2 are excluded owing to earlier operation for ulcer. That leaves 220 patients, of whom 172 have been treated for chronic ulcer and 48 for acute hemorrhage. Of the 144 duodenal ulcers, 114 involved men and 30 women. The 28 gastric ulcers were equally distributed between men and women. Of 169 ulcer patients examined for occult bleeding, 74 were positive and in 95 blood was not detected. The therapeutic results were not influenced by the presence or absence of occult bleeding. The authors

designate as recovered those who are entirely free from symptoms and who can eat all types of food. In the group called improved the patients occasionally have dyspepsia, but this is not so pronounced that later treatment has been necessary. As not cured they designate patients later requiring operation and those who suffer from more or less continual dyspepsia in spite of a strict regimen, often showing a persistence of the ulcer roentgenologically. The follow-up study revealed that 65 had recovered, 76 were improved and 79 were not cured. Relapses generally occur during the first three years. The minimum observation period of three and a half years may therefore be regarded as sufficient. Therapeutic results in cases of acute hemorrhage were better than in chronic ulcer. Two series of medical treatment were generally tried before surgical treatment was recommended. In view of the low percentage of permanent recovery with medical treatment, the authors advise young patients with chronic ulcer to have an operation sooner than has hitherto been the practice.

Intravenous Liver Extract in Treatment of Cirrhosis of Liver.—Rawls and Ancona report 22 patients, 18 with biliary cirrhosis, who received treatment for four months or longer. Diagnosis was established by clinical observations and laboratory tests. Treatment consisted of administration of crude liver extract, the water soluble, alcohol insoluble portion of dry powdered liver, which has been rendered free of pyrogens and toxic amines. To test for sensitivity, 0.1 to 0.2 cc. of the undiluted extract is given intramuscularly. If within thirty minutes there is no reaction such as headache, dyspnea, flushing of the skin or other signs of sensitivity, 1 cc. of the liver in 19 cc. sterile pyrogen-free isotonic sodium chloride solution is given intravenously at the rate of 2 cc. per minute. If there is no reaction, the dose is increased gradually. In the presence of sensitivity, as denoted by headache, dyspnea, flushing or other untoward reaction following the intramuscular test dose, desensitizing doses are employed. Return of appetite is usually one of the first indications of improvement and frequently is followed by improvement in all symptoms. Eighteen patients have survived fifteen months or longer; 4 have been able to continue without treatment for periods of four to twelve months. These results indicate that the intravenous administration of crude liver extract has a beneficial effect on the nutritional state in patients with cirrhosis. The extract is safe to administer provided that proper precautions are taken.

Rupture of Tympanic Membrane.—Folbre reports observations on 55 cases of perforation of the ear drum due to blast that occurred during the war. In approximately half of the cases there were infections, and in 2 of these mastoiditis developed. One of the most important observations in the treatment of the ear drum perforations was the way the perforations can be stimulated to heal by the use of trichloroacetic acid and an artificial drum of cigaret paper. All perforations of small to moderate size which showed little or no sign of healing were treated by applying a sterile piece of cigaret paper. It is picked up by touching it with a cotton-tipped applicator wet with sterile saline solution. The paper is wiped onto the perforation. Another cotton-tipped applicator wet with trichloroacetic acid is touched against the paper on the perforation. The acid spreads quickly through the paper and cauterizes the edges of the perforation. Pain resulting from this method matters less because the paper is already in place and the patient is no longer required to hold still. About 75 per cent of the perforations on which the paper was applied healed.

New Operation for Treatment of Hydronephrosis with Aberrant Artery.—Stewart felt that the standard operation for hydronephrosis due to obstruction from a lower polar artery did not satisfy the ideals of surgery. Ten years ago, when operating for this condition on a boy, aged 15 years, it was found that the lower polar artery was so large as to constitute the chief arterial supply to the kidney. Division of this vessel was out of the question. The author decided on a new procedure, in which the kidney is "molded" so that the lower pole carries the aberrant artery upward into close proximity with the normal renal artery. The anatomic relationships of infancy are thus reestablished, and the natural changes in the anatomy which have occurred with growth are reversed. The operation was successful and today, ten years later, this young man remains in perfect health. Encouraged by this initial success, the author used the operation at first for cases similar to the original one with large polar arteries. As these continued to give uniformly successful results, he extended use of the operation to all cases judged worthy of conservative surgical mea-

sures. He shows that this procedure secures a permanent relief of the obstruction and that the manipulation of the renal parenchyma does not interfere with its excretory function. This operation, which does not entail opening the pelvis or ureter, avoids many of the dangers inherent in the older plastic operations, while it maintains the integrity of the renal arterial supply.

Penicillin for Infected Hands.—D'Abreu and his associates present observations on 185 patients with infected hands and aim to assess the value of a method of administering systemic penicillin which can be used on outpatients. Seventeen of the patients received penicillin, whereas 168 did not. The average loss of duty for these 168 patients was 20.3 days, whereas for those treated with penicillin the average was 8.9 days—a saving of 56 per cent compared with the nonpenicillin series. It is suggested that administration of penicillin in all severe infections of the hand, both in the early stages and after any necessary surgical intervention, should be adopted as a routine method of treatment. A dosage of 125,000 units of penicillin in oil or 300,000 units in aqueous solution twice a day has been found adequate.

Abacterial Pyuria and Reiter's Syndrome.—According to Baines, joint effusions have been reported in several cases of abacterial pyuria. If the cases reviewed by him in this paper had come under observation at a time when the urethritis and cystitis were present, but before the arthritis developed, they would have been classified as abacterial pyuria and not as Reiter's syndrome. It would appear that there is nothing to distinguish the sterile urethritis, cystitis, prostatitis and pyelitis found in Reiter's syndrome from abacterial pyuria. It has repeatedly been stressed that all cases of abacterial pyuria respond to neoarsphenamine therapy. The author has found the same response, as far as the urinary symptoms are concerned, in those cases of Reiter's syndrome that he has treated with neoarsphenamine. The joint lesions did not appear to be greatly affected, though they all cleared up more quickly than might have been expected, and new lesions did not appear after the completion of the neoarsphenamine treatment. The author has suggested elsewhere that abacterial pyuria is a colitis, if not a venereal, disease and that the whole urinary and genital tract may be infected by an organism gaining entrance through the urethra. The other symptoms observed in Reiter's syndrome may be a further extension of the same process. In 2 cases of Reiter's disease in which cystoscopic observations were made in the acute stage, the findings were similar to those in abacterial pyuria.

Sulfonamide Photosensitivity: Relation to Vaccination Reaction.—Watkinson and Hillis say that in the control of streptococcal infections in a Royal Air Force station sulfonamide drugs were administered prophylactically in a dosage of 2 Gm. a day for ten days to 470 persons. A high incidence (34.6 per cent) of photosensitization rashes occurred, due to a combination of three factors—the sun, vaccination and sulfanilamide. The highest incidence of rashes was found in men recently vaccinated and coincided with the development of the pustular stage, even when this occurred after administration of the drug had been suspended. Rashes did not appear in persons in whom vaccination had failed or was refused. All the rashes were evanescent; but true sulfonamide sensitivity remained a possibility, and subjects with rashes were advised to warn physicians in the future of the possibility of their being sensitized. The mechanism of the phenomenon is obscure, the drug, the vaccination lesion and light all playing a part.

from the throats of most patients in close contact with persons who have had rheumatic fever suggests a practical method of protecting the latter group from infection due to the beta hemolytic streptococcus. Further observations are needed to ascertain whether prompt penicillin therapy for acute infections due to hemolytic streptococcus in subjects with rheumatic fever may decrease the likelihood of a recurrence of rheumatic fever.

- Study of Digestive Capacity of Stomach by Means of Physicochemical Methods. S. S. Cytronberg, A. L. A. Del Castillo and A. de Lachica.—p. 721.

Medical Treatment of Peptic Ulcer.—Kahrs and Schrumph present a follow-up study of 239 cases of gastric and duodenal ulcer treated during the period 1938 to 1942. Seventeen patients died during the observation period and 2 are excluded owing to earlier operation for ulcer. That leaves 220 patients, of whom 172 have been treated for chronic ulcer and 48 for acute hemorrhage. Of the 144 duodenal ulcers, 114 involved men and 30 women. The 28 gastric ulcers were equally distributed between men and women. Of 169 ulcer patients examined for occult bleeding, 74 were positive and in 95 blood was not detected. The therapeutic results were not influenced by the presence or absence of occult bleeding. The authors

designate as recovered those who are entirely free from symptoms and who can eat all types of food. In the group called improved the patients occasionally have dyspepsia, but this is not so pronounced that later treatment has been necessary. As not cured they designate patients later requiring operation and those who suffer from more or less continual dyspepsia in spite of a strict regimen, often showing a persistence of the ulcer roentgenologically. The follow-up study revealed that 65 had recovered, 76 were improved and 79 were not cured. Relapses generally occur during the first three years. The minimum observation period of three and a half years may therefore be regarded as sufficient. Therapeutic results in cases of acute hemorrhage were better than in chronic ulcer. Two series of medical treatment were generally tried before surgical treatment was recommended. In view of the low percentage of permanent recovery with medical treatment, the authors advise young patients with chronic ulcer to have an operation sooner than has hitherto been the practice.

Intravenous Liver Extract in Treatment of Cirrhosis of Liver.—Rawls and Ancona report 22 patients, 18 with biliary cirrhosis, who received treatment for four months or longer. Diagnosis was established by clinical observations and laboratory tests. Treatment consisted of administration of crude liver extract, the water soluble, alcohol insoluble portion of dry powdered liver, which has been rendered free of pyrogens and toxic amines. To test for sensitivity, 0.1 to 0.2 cc. of the undiluted extract is given intramuscularly. If within thirty minutes there is no reaction such as headache, dyspnea, flushing of the skin or other signs of sensitivity, 1 cc. of the liver in 19 cc. sterile pyrogen-free isotonic sodium chloride solution is given intravenously at the rate of 2 cc. per minute. If there is no reaction, the dose is increased gradually. In the presence of sensitivity, as denoted by headache, dyspnea, flushing or other untoward reaction following the intramuscular test dose, desensitizing doses are employed. Return of appetite is usually one of the first indications of improvement and frequently is followed by improvement in all symptoms. Eighteen patients have survived fifteen months or longer; 4 have been able to continue without treatment for periods of four to twelve months. These results indicate that the intravenous administration of crude liver extract has a beneficial effect on the nutritional state in patients with cirrhosis. The extract is safe to administer provided that proper precautions are taken.

Rupture of Tympanic Membrane.—Folbre reports observations on 55 cases of perforation of the ear drum due to blast that occurred during the war. In approximately half of the cases there were infections, and in 2 of these mastoiditis developed. One of the most important observations in the treatment of the ear drum perforations was the way the perforations can be stimulated to heal by the use of trichloroacetic acid and an artificial drum of cigaret paper. All perforations of small to moderate size which showed little or no sign of healing were treated by applying a sterile piece of cigaret paper. It is picked up by touching it with a cotton-tipped applicator wet with sterile saline solution. The paper is wiped onto the perforation. Another cotton-tipped applicator wet with trichloroacetic acid is touched against the paper on the perforation. The acid spreads quickly through the paper and cauterizes the edges of the perforation. Pain resulting from this method matters less because the paper is already in place and the patient is no longer required to hold still. About 75 per cent of the perforations on which the paper was applied healed.

Book Notices

Annual Reprint of the Reports of the Council on Pharmacy and Chemistry of the American Medical Association for 1946, with the Comments that Have Appeared in the Journal. Cloth. Price, \$1. Pp. 137, with 4 illustrations. American Medical Association, 535 N. Dearborn St., Chicago 10, 1947.

This volume presents not only reports on the medicinal articles which the Council has found unacceptable for inclusion in New and Nonofficial Remedies during the past year but also status reports on therapeutic advances and procedures and on promising drugs.

Widespread attention was attracted by publication in THE JOURNAL of the report of Dr. S. M. Feinberg, "Histamine and Antihistaminic Agents," sponsored by the Council, which appears in this volume. Since it was first published the Council has accepted for inclusion in New and Nonofficial Remedies the two new agents evaluated in the article, diphenhydramine hydrochloride and tripeleminamine hydrochloride ("benadryl hydrochloride" and "pyribenzamine hydrochloride," respectively).

During the past year the Council has reported on three unacceptable preparations: Cabasil, an unscientific mixture, the exploitation of which for use in a multitude of disease conditions is aptly expressed in the title, "Quackery Unlimited"; the pseudoscientific ethylene disulphonate (Allergosil brand), a preparation of highly uncertain composition exploited to physicians for use in allergic conditions; and Formula A-1, covered in a joint report of the Council on Pharmacy and Chemistry and the Council on Industrial Health as an expensive but poor substitute for acetylsalicylic acid and citrate of magnesia. Formula A-1 has been cleverly exploited to industrial concerns for use in reducing absenteeism due to colds.

Attention is called to the several reports on the adoption of generic designations for drugs proposed or marketed under protected (proprietary) names. Not all such actions of the Council have been the subject of separate published reports; the recognized terms have appeared in the published descriptions of the drugs when accepted and will be inserted in another Council publication, New and Nonofficial Remedies, as adoption of such designations for already accepted products proceeds. This is in accord with a recent revision of the Council's rule governing the names of accepted preparations.

Physikalische Medizin in Diagnostik und Therapie. Von Wolfgang Holzer, Professor Dr. Med. et Dr. Inc., Vorstand der Psychiatrisch-Neurologischen Universitätsklinik Graz und des Entwicklungslaboratoriums für physikalische Medizin der Nervenklinik in Graz. Band II, Bücherei der physikalischen Medizin. Fifth and sixth edition. Cloth. Price, \$9. Pp. 769, with 379 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; Wilhelm Maudrich, Spitalgasse 1B, Wien IX/2, 1947.

This book indicates the magnitude to which physical medicine has grown. The author does not slight technical details and fundamental questions in any of the areas explored. The treatment of electrophysiology, especially electroencephalography, is detailed and modern. Curves are drawn with exactitude, and equations are given in complete and intelligible form. A fine tradition of scholarship, which presupposes on the one hand a precise use of mathematics and, on the other, a correct use of modern languages, is well exemplified in this book. It is particularly illustrated in the long section on diathermy and short wave therapy, probably one of the best summaries of this subject available. This section alone is illustrated by sixty-four figures, all apparently original. They are about equally divided between diagrams explaining theoretic concepts and sketches or photographs showing practical applications.

The author at times traverses shaky ground. On page 472 he refers to the administration of radioactive substances in baths, beverages, compresses and inhalations. A more critical appraisal of the results that have been ascribed to these treatments is desirable. The following statement was made recently by one expert on the subject: "Radium water is not just something to look at askance. If it has any radioactive material in it, it is deadly." While the author repeatedly mentions cautions and the possibility of bad results, there is little indication of the benefits expected as a reward for subjecting the patient to these

dangers. Reports of good results in arthritis and neuritis should be viewed with suspicion.

The style of this book is readable; the sentences are short and unaffected. A 21 page bibliography furnishes an adequate key to the relevant literature. The index is complete and is happily free from exasperating cross references ("Blood pressure: see Pressure, blood") so often encountered in other works.

Recent Advances in Public Health. By J. L. Burn, M.D., D.Hy., D.P.H., Medical Officer of Health and School Medical Officer, City of Salford. Cloth. Pp. 409, with 82 illustrations. J. & A. Churchill, Ltd., 101 Gloucester Place, Portman Square, London, 1947.

This book covers a wide set of subjects classified as recent advances in public health. Its contents satisfactorily cover the rapidly changing social scene and the effect on the public health. Individual, community and environmental health are covered with thoroughness and dispatch; to the American health officer, this book should prove interesting reading and a valuable asset in his daily duties.

The chapter on rural epidemiology is altogether too short, but the author's observations indicate what a fertile field there is in determining the causes and the modes of spread of diseases in rural areas. The lesson to be learned is that every practicing physician is a practical epidemiologist however busy his life.

The briefness of some chapters, such as that on immunization against smallpox may be disappointing to American readers.

The chapter on smokeless air should interest the health officers of communities where advocates of smoke control become unpopular with industry. Dr. Burn makes the observation that millions of tons of soot fall in Great Britain, more than half coming from domestic fires. One chapter has an altogether too brief description of milk pasteurization, and only one method is mentioned. Lapses of procedure of this type are few indeed and generally do not detract from the book's usefulness to health officers.

Qualitative Analysis by Spot Tests: Inorganic and Organic Applications. By Fritz Feigl, Eng., Dr.Sc. Third English edition translated by Ralph E. Osper, Ph.D., Professor of Chemistry, University of Cincinnati, Cincinnati. Cloth. Price, \$8. Pp. 574. Elsevier Publishing Co., Inc., 215 Fourth Ave., New York 3, 1946.

Spot test analysis may one day attain considerable importance for clinical chemistry, as the tests are carried out on small quantities of material without aid of elaborate equipment. When such time arrives, this book will be one of the few available foundations for the expansion of these methods.

The book contains chapters on (1) working methods and special aids in spot test analysis, (2) tests for metals, (3) tests for acid radicals, (4) tests for free elements, (5) systematic analysis of mixtures by spot reactions, (6) use of spot reactions in qualitative organic analysis, (7) application of spot reactions in tests of purity, examination of technical materials and studies of minerals; a bibliography on the application of spot reactions for special scientific or technical purposes and a tabular summary of the limits of identification obtained by spot tests are included.

Each test is prefaced by a few lines on theory and limitations of the test, followed by details of the procedure, limits of identification, concentration limit and reagents used.

Précis de diagnostic hématologique. Par G. Hemmeler, privat-docent à la Faculté de médecine de l'Université de Lausanne. Préface du Prof. Dr. Louis Michaud. Paper. Price, 700 francs. Pp. 168, with 60 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6^e; F. Roth & Cie, Lausanne, 1947.

This is a concise, well written and well edited book, containing the essential features of the diseases involving red and white blood cells and platelets. A short section on technical methods, followed by a systematic short description of the disease entities, is included. A résumé follows each section, including clinical symptoms, blood and marrow picture and treatment. The colored plates are satisfactory, comprehensive and serviceable. The book has a remarkable amount of material in condensed form. A bibliography is not given. The compilation should serve as a handy work for quick reference in differential diagnosis of "diseases of blood." This is its primary purpose.

treatment. In the early stages fever therapy (malaria or intravenous typhoid inoculation) if the patient is robust enough seem to do good.

Most important is the local treatment: atropine 1 per cent two or three times a day for the uveitis which always accompanies the keratitis, heat, ethylmorphine hydrochloride, very dark glasses (do not bandage). In the late stages it is customary to use irritating applications designed to hasten the clearing of the cornea, which takes place spontaneously: dry or moist heat, ethylmorphine hydrochloride and yellow oxide of mercury are used. Their benefit is doubtful.

ESOPHAGEAL ULCER

To the Editor:—A patient aged 59, employed as a repairman of large laundry washing machines, found it necessary for him to enter the machine to make the proper repairs. While working over the drain of the machine a gust of fumes appeared. The patient began to cough and only with difficulty was able to get out of the machine. All that night he coughed and complained of pain in his chest and nausea. The cough subsided in a week, but he complained of severe pains across the chest, front and back. The pains continued and increased in severity. The patient then noticed that the pain increased immediately after food. An electrocardiogram was negative. A Sippy diet and the use of alkaline and antispasmodic drugs gave no relief. A gastrointestinal series showed a dilatation of the esophagus at the cardiac orifice of the stomach and a narrowing below the dilatation. The rest of the gastrointestinal tract was negative. I have obtained a partial list of the ingredients of this cleansing powder, and it is as follows: sodium acid bifluoride, sodium silica fluoride and sodium hypochlorite. The pathologic process is an ulcer at the lower part of the esophagus. Could inhalation of the aforementioned substances cause this ulcer? The patient was perfectly well until this accident occurred.

M.D., New York.

ANSWER:—Certain compounds of fluorine are highly toxic. It is well established that under some circumstances peptic ulcers may follow damage such as that from severe cutaneous burns. However, the Curling type of ulcer is almost invariably at the duodenal end of the stomach. In the light of present knowledge of the toxicity of fluorine compounds, it is unlikely that an esophageal ulcer with dilatation and narrowing of the esophagus might be attributed to the episode described. Peptic ulcers do appear on a psychosomatic basis. It is conceivable that undue apprehension related to the pulmonary state may have been a factor in the causation of the esophageal ulceration. The probability of such is remote.

LOW GRADE DIABETES

To the Editor:—A man aged 74 has complained for two months of bad taste and a tight feeling in the throat during the night and early morning; never during the day. I have checked the blood count, blood sugar, nonprotein nitrogen, Wassermann reaction and the urine. The stomach has been x-rayed, and a complete neurologic examination has been made. Blood sugar has been 167 = 164; the last, 117 on a diet. No insulin has been given. Tonsils and teeth have been removed. What would you suggest?

George C. Stimpson, M.D., Poy Sippi, Wis.

ANSWER:—The patient would seem to have a low grade diabetes mellitus, which could be confirmed by a sugar tolerance test. The condition need not include glycosuria or ketonuria. The symptoms are characteristic. A feeling of dryness is most common and may be due both to loss of fluid through the kidneys and to inhibition of salivary secretion. The tendency may be accentuated at night because of absence of fluid intake and possible mouth breathing. In mild diabetes the signs of coated tongue, red mucous membranes and evidences of a low resistance to infection may not be present. They would be less obvious with the teeth gone. They may be due, when present, partly to associated vitamin deficiencies. Diet would seem sufficient to control the diabetes at present. Vitamin concentrates could wisely be given.

PREMATURE WRINKLING OF SKIN OF FACE

To the Editor:—Can you tell me the most effective method to treat wrinkles? My patient is a man of 35 whose face is prematurely wrinkled.

M.D., California.

ANSWER:—Wrinkling is the result of degeneration of the elastic tissue, loss of subcutaneous fat and loss of normal fluid content. Excessive wrinkling of the face may be due to distortion of the skin by the underlying musculature.

In any case there is no satisfactory local method of treatment. Temporary improvement may follow the use of applications which cause superficial inflammation, but the end result is likely to be an increase in the wrinkling.

If the wrinkling is so pronounced as to be considered a deformity, plastic surgery might be of benefit.

BASAL CELL CARCINOMAS

To the Editor:—I am having difficulty in obtaining standard insurance. I had a small basal cell carcinoma of the upper lip removed eighteen months ago with no evidence of recurrence up to the present moment. However, despite this the insurance companies insist on giving out only substandard insurance. Are basal cell tumors correctly classified as "malignant"? What is the likelihood of recurrence of a basal cell tumor after surgical excision? Are there any statistics which show that the incidence of malignant neoplasms of any type is greater in patients who have had basal cell carcinoma than in the general population?

Daniel K. Adler, M.D., Syracuse, N. Y.

ANSWER:—Basal cell carcinomas are malignant. The likelihood of recurrence of a basal cell carcinoma after adequate excision is exceedingly remote. No evidence is available to the effect that the incidence of cancer (excepting cancer of the skin) is greater in patients who have had basal cell carcinoma than in the general population.

NAIL BITING

To the Editor:—A boy aged 6½ years chews his nails. He is nervous, always on the go, very active and intelligent. Can he be trained to overcome the habit?

Arthur E. Perley, M.D., Waterloo, Iowa.

ANSWER:—Chewing nails is a puerile habit and may be associated with other habits of childhood such as thumb sucking, masturbation and finger sucking, although less frequent than the others. It is seen in emotionally unstable and tense children who find some feeling of relief by chewing their nails. There is no danger in the habit. Most of the children quit it of their own accord when they start to meet others socially. Only a few continue to chew or bite their nails in adult life. There is no specific treatment. A rather kindly, pleasant and understanding attitude with the giving of a reward if and when the chewing stops for a period of at least six months may work wonders. At least, this should be tried. One should not threaten or be exceedingly critical of this type of boy, because he will continue to do it.

COMPLICATIONS DUE TO PESSARY

To the Editor:—I have a patient who retained a rubber pessary in her vagina for about six years. What are the usual complications that may occur?

James Frenkil, M.D., Baltimore.

ANSWER:—While it is assumed that the pessary in question is a hard rubber one, even soft rubber pessaries may cause complications. A properly fitted pessary is less likely to cause pressure necrosis. Pressure necrosis may cause a complete dissolution of the protective tissue with resultant inflammatory reaction. Perhaps, more commonly, pessaries react as foreign bodies, producing a vaginitis and becoming encrusted. Any inflammatory reaction produced might give secondary symptoms, particularly if there is lymphatic spread. For instance, it might result in urinary bladder symptoms. Attempts at coitus may cause displacement or change of position of the pessary, as well as trauma.

INFLAMMATION OF THE SWEAT GLANDS

To the Editor:—A patient has a chronic, suppurative folliculitis of both axillae which has been present for three years. Urinalysis is negative, the blood count is normal and guinea pig inoculation is negative for tuberculosis, showing mixed infection due to staphylococci and streptococci. Treatment has been with penicillin, sulfadiazine, wet dressings of tyrothricin, irrigations with chloramine-T ("chlorazene") incision and drainage of abscesses and a three months' treatment with staphylococcus toxoid. The radiologist was not enthusiastic about giving roentgen therapy. Is there any other treatment that might be used to clear up this condition?

R. E. Atkinson, M.D., Crestline, Calif.

ANSWER:—The condition described is typical of that known as hidradenitis suppurativa, inflammation of the sweat glands. All the forms of treatment mentioned are indicated but apparently have been without result. Roentgen radiation is recognized as one of the most effective methods of treatment.

TONSILLECTOMY IN MONGOLOID CHILDREN

To the Editor:—Is there any indication against the removal of the tonsils in mongoloid children? A patient of mine aged 4 years suffers from hypertrophy of the tonsils.

Samuel Newman, M.D., Danville, Va.

ANSWER:—Mongoloid children frequently have hypertrophy of the tonsils. They stand an operation usually as well as any normal child with hypertrophic tonsils. It is, however, inadvisable to perform such an operation too early in childhood. A mongoloid of 4 is really not more than a normal child of 2 to 3 years, and the child should be treated according to his developmental age and not his chronologic age.

REDUCTION OF MORTALITY FROM PREMATURE BIRTH

Some Practical Measures

LFW. A. KOCH, M.D.
C. A. WEYMULLER, M.D.
and
ELIZABETH JAMES, M.D.
Brooklyn

The purpose of this paper is to present our concept of certain problems of prematurity and to discuss the practical measures instituted at the Long Island College Hospital to improve our results in this field.

We consider a premature infant to be any infant born alive who weighs 2,500 Gm. (5 pounds, 8 ounces) or less, whose heart beats or who moves. No lower limit of viability is allowed. This definition is that which is accepted by the American Academy of Pediatrics¹ and must be rigidly adhered to by all institutions and agencies for reports and tabulations if experiences are to be comparable.

That prematurity is a leading cause of death in the United States has recently been reemphasized by the United States Children's Bureau (Dunham²) in an analysis based on reports of the United States Bureau of Census for the year 1944 (the most recent year in which figures are available). Premature birth takes a higher toll of infant life than any other pediatric condition, and it is one of ten leading causes of death among the general population. It was given as the cause of death of 33,120 infants in 1944, most of whom (32,065), as would be expected, died during the first month of life (the neonatal period).

It is gratifying to find now that the national neonatal mortality rate from premature birth has fallen from 14.9 per thousand of all live births in 1933 to 11.4 in 1944. Therefore, infants born prematurely in the United States in 1944 enjoyed about a 20 per cent better chance of survival than those born in 1934.

However, it is startling to note (chart 1) that more than one half of the deaths from prematurity occur during the first twenty-four hours. Such a circumstance clearly indicates that the measures which have been effective of improvement in the past decade should be even more sharply directed against the menaces of this first twenty-four hour period. That period is the

one in which the hazards of prematurity are directly reflective of prenatal and natal occurrences and are greatly influenced by the efforts of the obstetrician.

HOW THE OBSTETRICIAN MAY AID IN REDUCING MORTALITY FROM PREMATURE BIRTH

Mortality from premature birth can obviously be reduced in but two ways, either by an actual over-all reduction in the incidence of premature birth or by improvement in methods of care of the premature infant after birth. The obstetrician not only is entirely responsible for the reduction of the incidence of premature birth but is also concerned in a great measure with the results of pediatric efforts.

The accepted morbidity studies reveal that the majority of deaths of premature infants which occur during the first twenty-four hours are the result of accidents associated with birth, oftenest due to trauma and asphyxia. Such mishaps predominate among infants who weigh less than 1,500 Gm. (3 pounds, 5 ounces). Therefore, not only must the efforts of obstetricians be directed toward lowering the over-all incidence of premature birth, but they must strive persistently for the prolongation of intrauterine life so that the infants' weights will fall within the higher weight groups.

Beck³ stated that the obstetrician must look on the birth of these smaller premature infants as an obstetric failure, a responsibility comparable to having a stillbirth. Accordingly, our first recommendation is the adoption of the measures which he recommended to help the obstetrician in reducing the total incidence of premature birth and in assuring a more viable infant. The high points from his excellent review were:

1. Adequate supervision of the hygiene of pregnancy
2. Proper advice concerning diet, coitus, rest and exercise
3. Immediate notification of the obstetrician whenever any untoward symptoms occur
4. Early discovery of the presence of syphilis and vigorous treatment for it throughout pregnancy
5. Prevention of congestive failure in cardiac disease through joint supervision by cardiologist and obstetrician
6. Determination of the size of the child by means of roentgen ray. Also, consultation with another competent obstetrician before interrupting pregnancy by artificial means
7. Elimination of morphine, scopolamine, barbiturates and general anesthesia in all labors in which prematurity is involved
8. The administration of vitamin K to the mother before pregnancy is interrupted and to all premature infants immediately after birth

Read before the Section on Pediatrics at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

1. Round Table Discussion on Prematurity, *J. Pediat.* 8:104-130, (Jan.) 1936.

2. Dunham, E. C.: Unpublished material.

3. Beck, A. C.: Obstetricians' Responsibility for Hazards of the First Days of Life with Special References to Anoxia and Prematurity, *Am. J. Obst. & Gynec.* 51:173-183 (Feb.) 1946; How Can the Obstetrician Aid in Reducing Mortality of Prematurely Born Infants? *ibid.* 42:355-364 (Aug.) 1941.

9. Preservation of the membranes as long as possible and episiotomy to protect the premature infant from the pressure effects of labor

10. Spontaneous delivery of the second twin and avoidance of version and extraction whenever possible

11. Postponement of the tying of the cord until it stops pulsating in order that the child may receive as much blood from the placenta as possible

12. Reception of the newly born premature infant in a tub of warm water to prevent chilling while waiting for the cord to stop pulsating

HOW THE PEDIATRICIAN MAY AID IN REDUCING MORTALITY FROM PREMATURE BIRTH

The United States Children's Bureau⁴ has published minimal standards for the care of premature infants in hospitals and standards and recommendations for hospital care of newborn infants, and these publications decidedly deserve careful study. This bureau reports an appalling absence of such standards in many approved hospitals. In a few localities certain requirements have been established by law.

In general, hospital standards have been developed and maintained in the United States mainly by the organized medical profession and not by legal authority.

Chart 1.—Age at death of infants that died from premature birth, United States, 1944.—Federal Security Agency, Social Security Administration, United States Children's Bureau (based on data from United States Bureau of the Census).

Therefore it is urged that consideration be given by appropriate committees to the formation and adoption of such standards as requirements in rating and classifying all hospitals which have a maternity service.

While much of the remainder of this discussion concerning measures which have reduced the mortality in premature infants will be common to all improved services, we wish especially to point out those which we believe have been most effective in our own experience. We will not detail our opinions on incubation, nutrition, individual therapy, time of discharge and follow-up care, because they are those generally accepted.

The prematurely born infant's chance of survival at the Long Island College Hospital has improved approximately 30 per cent during the past ten years, and our survival rates compare favorably with reports from other centers. It is our belief that new measures employed in our delivery rooms and extensive alterations in construction and nursing procedures in our nursery units, plus increased facilities and application

of diagnostic procedures are the factors which have been responsible for our improved results.

1. *The Delivery Rooms.*—Our hospital delivery rooms have in readiness at all times a heated crib for the reception of premature infants. In all cases in which a premature birth is expected, the infant is received directly into a warm bath, from which it is ordinarily not removed until it is transported to its nursery bed. Facilities are in readiness for resuscitation and the administration of oxygen. It is our custom to administer oxygen continuously to all prematurely born infants during the first hours after birth and as frequently thereafter as may seem indicated. In several instances we have utilized the services of the department of bronchoscopy before the infant was removed from the delivery room and with such gratifying results that we feel this service should be more frequently used.

2. *The Nursery Unit for Premature Infants.*—It is agreed that the ideal plan for the care of the premature infant would be to have each infant in a separate unit, under the care of its own physician, preferably a pediatrician, and with its own specially trained corps of nurses. That this is generally impossible is admitted.

It is also agreed that a special hospital room designed for premature infants containing not more than 4 such infants as recommended by the United States Children's Bureau⁵ would be the next choice in desirability. However, this plan requires three nurses having no other assigned duties for continuous twenty-four hour service. It also presupposes a full census or bed occupancy for economical and full nursing efficiency. The plan is inelastic and would seem too costly for many hospitals caring for less than 1,500 births annually. A further objection to this plan would seem to be the practical certainty of complete spread of infection to all premature infants in the unit should 1 infant contract a transmissible infection.

It will be evident that attempts to improve facilities for the care of these small infants will be somewhat more difficult in the hospitals with limited space and limited administrative funds. The Long Island College Hospital is a general hospital with limited endowment, consisting of five hundred beds and serving the populous waterfront district of Brooklyn. About 1,500 infants are born annually on our maternity service.

Since 1937 our nurseries have been altered in a rather revolutionary way. These changes were detailed by one of us (Charles A. Weymuller⁶) before this section at its last meeting. We feel that these changes have been in a large measure responsible for our improved results in premature births. Their practicality and inexpensiveness, as well as their success, would seem to justify their review.

Prior to 1937, our nurseries for newborn infants consisted of two large rooms with common weighing, bathing and storage facilities and with an adjacent similar room which served as an isolation unit. The premature infants were cared for in heated cribs in these nurseries, and so were subjected to the numerous actual and potential hazards of such a common arrangement.

4. The Expectant Mother, Children's Bureau Folder 1, United States Department of Labor, Children's Bureau, December 1943. Dunham, E. C., and Crane, M. M.: Standards and Recommendations for Hospital Care of Newborn Infants, Full-Term and Prematures, Publication 292, United States Department of Labor, Children's Bureau, 1943.

5. Dunham, E. C., and others: Plan for Hospital Unit for Premature Infants, Bulletin 9, United States Department of Labor, Children's Bureau, 1942.

6. Weymuller, C. A., and others: Protection of Newborn Infants, J. A. M. A. 133:78-84 (Jan. 11) 1947.

Since 1937 the following corrective measures have been completed:

(1) We have made our nursery units as small as our physical plant would permit (chart 2). Each main unit consists of a room containing sixteen cribs, an adjoining but separate room for weighing and bathing and an examining room partitioned off for the use of physicians. We now have four such main units besides a comparable isolation unit. If we had complete freedom of action we would have eight such clean units containing 8 infants each. The cribs of each unit are arranged in two groups of eight, affording seven beds for term infants and one incubation bed for the premature child. These beds occupy the entire duties of one nurse and are never interchanged.

(2) (a) Unnecessary contacts with visitors have been reduced by limiting visiting hours for ward patients, by the masking and gowning of visitors and by rope barriers which separate them from the beds in each public ward. Visiting hours for private patients have been restricted so far as public opinion has permitted.

(b) Nurses wear masks and gowns while caring for infants in the nurseries. When they are about to come on duty in the nurseries their throats are cultured. If dangerous organisms are found, the nurse is relieved of her duties.

(c) A physician must wear mask, gown and sterile gloves on entrance to any nursery for newborn infants. He must examine the infant in the special examining room attached to every unit unless there is an emergency which takes him into the nursery proper. If the physician passes from one unit to another, he must change his mask, gown and gloves for every unit entered. House officers are assigned to individual nursery units and are not shifted unless they are ill or terminate their service in the nursery. If they become ill, they are relieved of their duties and are studied to ascertain whether their illness will in any way affect the infants who have been under their care. If so, the nursery affected is quarantined, and the infants in it are treated accordingly.

(d) Ward maids and cleaning women in the nurseries are subject to the same regulations as nurses and physicians and are rigidly supervised by both.

(e) Every nursery unit has in its examining room complete medical equipment, so that no contamination can occur by way of stethoscopes, otoscopes or other instruments which might be brought in by the attending or house staffs.

(f) All bedclothing, diapers and clothes for the infants in the nurseries are sterilized by autoclave. Each infant's supply for the day is stored in a shelf under his crib. Thus, only his own nurse comes in contact with his supplies. This is in sharp contrast with the usual practice of having a central supply room.

(3) The measures taken to prevent the spread of infection from infant to infant through an intermediary are as follows:

(a) The assignment of nurses who care for newborn infants has been changed so that one nurse cares for but 7 babies of full term and 1 premature baby. The nurse is assigned for complete care of these infants; that is, she takes them to their mothers to be nursed or gives them their milk mixtures or fluids, bathes them, weighs them and cares for them in every

particular. This personal, individualized service permits the nurses to know in detail the condition of the babies in their charge. If they follow the required technic, they cannot transmit any infection beyond their group, much less beyond the ward of 16 in which they function. This is one of the greatest improvements which we have made and is, we believe, unique.

(b) The formula room is in a section of the hospital entirely removed from the nurseries and from ill patients. It is so arranged that contamination from outside the hospital or from any unit in the hospital is reduced to the minimum. All materials and utensils which enter the formula room pass through the sterilizer, which extends through the wall between it and the anteroom.

(c) Once in the unit, these materials are made into milk mixtures, placed in sterile bottles, capped with sterile nipples and covered with sterile glass caps. Although sterile precautions are taken before and during preparation, it is nevertheless considered that there might be contamination by air, hands or otherwise. Therefore the milk mixtures and other fluids are again sterilized. Repeated cultures of mixtures so prepared have shown that they are sterile.

Chart 2.—Nursery for newborn infants, typical unit. Each nurse cares for 7 term and 1 premature infant. The cribs are never interchanged and no common utility room is required.

(d) A common utility room is not needed, because each unit has its bottle warmer, its sterilizer and scrub sink and plenty of utensils. As all utensils are cleansed and sterilized before they leave the unit, contamination cannot be spread to other nursery units or to the formula room.

(e) Proper isolation units are provided for observation of suspected cases. Infants who are known to have transmissible diseases are transferred to the pediatric ward, where rigid isolation technic is observed.

Therefore, if any infant in any unit has infection the following steps are taken:

The affected infant is immediately removed to the pediatric ward and isolated. The unit from which this infant came is closed to further admissions until the hospital physicians feel certain that new cases will not develop. The nursing and medical personnel of the unit involved carefully observe every exposed infant for the development of symptoms. When a contaminated nursery has been finally emptied through routine discharges or transfer to the pediatric services, it is thoroughly washed with soap and water and aired, and it is not reopened for twenty-four hours after cleansing. All cribs and mattresses are specially treated.

Since the changes outlined have been in effect we have noted a definite reduction in infant morbidity in

our nurseries. A careful study of some twenty thousand records is now being made to evaluate in detail our morbidity experiences before and since these changes were completed. We feel that, because of the extreme susceptibility and low resistance of the prematurely born infant, this reduction in morbidity has been greatly responsible for the decrease in the fatality rate of our premature infants.

3. *Diagnostic Facilities.*—We have provided all the accepted diagnostic aids of proved value in the study and management of the term infant, and the pediatric staff liberally utilizes them in the care of premature infants as well. These include facilities for bedside roentgenograms, bronchoscopic and urologic consultations, hematologic and immunologic studies (especially of Rh typing and agglutinations and the use of Rh-negative blood transfusions), blood chemical determinations and bacteriologic and pathologic studies.

4. *Records and Staff Supervision.*—Too frequently in the past the records of the premature infants in our own hospital were noted to be incomplete, which may or may not indicate that the necessary observations and procedures had not been made. There seems to be a special tendency among interns and even some staff physicians to neglect the premature infant. Routine diagnostic measures are sometimes omitted and too

Jan. 1, 1945, 9,084 living infants were born on the same service and 637 of these weighed less than 2,500 Gm., or an incidence of premature birth of 7.0 per cent. Of these infants who were prematurely born, 104 succumbed; a fatality rate of 16.3 per cent, which, as mentioned, represents an over-all improvement of approximately 30 per cent. These improved fatality rates are especially obvious when the percentage rates for each of the four standard weight groups are directly compared (the table).

Thus it will be seen that not only has our over-all fatality rate fallen since 1940, but a gratifying improvement has been made in each weight division.

While these improved results are, we feel, primarily due to the changes effected in our methods of caring for all infants in the nurseries for newborn infants, we feel that the obstetric procedures outlined previously have aided us immeasurably in reducing the fatality rate of the smaller infants. Although the actual incidence of premature birth has not been lowered and analysis reveals that the percentage incidence of birth of the smaller infants (1,500 Gm. or less) has not been materially decreased, we are convinced that in general these smaller infants are now more vigorous and show less morbidity than in the earlier years. It is possible that our present morbidity studies will support this impression.

SUMMARY AND CONCLUSIONS

The official definition of premature birth, "every living infant whose weight at birth is 2,500 Gm. (5 pounds, 8 ounces) or less," should be accepted by every hospital having a maternity service.

Mortality from premature birth is the chief cause of pediatric deaths in the United States.

Mortality rates from premature birth can undoubtedly be improved by obstetricians through a reduction in the total incidence of premature birth and especially by reducing the incidence of birth of infants whose weights are less than 1,500 Gm. (3 pounds, 5 ounces). Methods that may aid in effecting these aims are outlined.

A method for the care of premature infants in small nursery units containing 1 premature infant and 7 (or less) term babies is outlined. The infants in this unit receive their complete care from one nurse. The plan is fully discussed and is recommended for the smaller institution which cannot finance the added nursing cost of maintaining a separate unit for premature infants. The improved fatality rates since this plan has been adopted at the Long Island College Hospital are reviewed.

ABSTRACT OF DISCUSSION

DR. CHARLES C. CHAPPLE, Philadelphia: The paper by Koch and his group suggests some queries regarding the relative importance of various measures for the care of premature infants. For example, was infection a large or small factor in the mortality? In the Children's Hospital of Philadelphia, we use the same type of incubator for the care of premature infants as does the Long Island College Hospital, but we have no direct connection with an obstetric service. The infants are brought in from their homes or other hospitals. In ten years of use of this device, we have had a low morbidity with no infections of the respiratory tract whatever. The low morbidity is in spite of the fact that most of the care is given these infants by student nurses who are frequently changed, with but a single graduate nurse as ward supervisor, and that, for more than a year, it was necessary to keep the premature infants in an open ward with sick infants where well and sick alike

Fatality Rates Among Premature Infants at the Long Island College Hospital, 1924 to 1940 and 1940 to 1945

Period	Number of Live Births	Number Weighing 2,500 Gm. or Less	Incidence of Premature Births, Per centage	Fatality Rate					Total 2,500 Gm. or Less
				Less Than 1,000 Gm.	1,000-1,500 Gm.	1,501-2,000 Gm.	2,001-2,500 Gm.		
1924-1940	16,757	1,125	6.6	97.0	66.3	41.1	10.3		28.4
1940-1945	9,084	637	7.0	92.0	41.4	18.3	4.6		16.3

frequently diagnostic or therapeutic measures are not instituted until severe morbidity has developed, and then there is hesitation to carry out such measures because of the small size of the infant. Successful and life-saving bronchoscopic measures and major surgical procedures are now common experiences and should never be avoided because the patient is premature.

It is essential that the neonatal morbidity and mortality of the premature infants be carefully reviewed at the regular staff conferences with the joint attendance of all members of the pediatric, obstetric and pathology departments. In addition, we feel that all hospitals having a maternity service should make a yearly tabulation of their experiences in accordance with the accepted method of division into the four standard weight groups, which are those weighing less than 1,000 Gm., 1,001 to 1,500 Gm., 1,501 to 2,000 Gm. and 2,001 to 2,500 Gm. This will allow each hospital to evaluate accurately and compare its results with those in other institutions.

MORTALITY FROM PREMATURE BIRTHS AT THE LONG ISLAND COLLEGE HOSPITAL

From Jan. 1, 1924, until Jan. 1, 1940, 16,757 living infants were born at the Long Island College Hospital, and 1,125 of these weighed 2,500 Gm. (5 pounds, 8 ounces) or less at birth, an incidence of premature birth of 6.6 per cent. Of these 1,125 prematurely born infants 320 died, an over-all mortality from premature birth during this sixteen year period of 28.4 per cent.

From 1940, a period representative of completed changes in our nursery units for newborn infants, to

were cared for by the same nurses. This was possible because the incubators circulate only outdoor air and the infants in them are completely isolated except from contact with the nurse's hands, which she washes frequently and carefully. Since the hands are the only possible contact, the nurse does not wear mask or gown; and as the temperature and humidity maintained about each infant are independent of the ward, the ward is kept at a comfortable temperature, with no attempt to reach that required by the infants. Consequently fewer infections of the respiratory tract develop among the nurses. The gross mortality of our premature infants has been greatly reduced, largely because of the elimination of respiratory infection. Dr. Koch and associates have covered the subject of the reduction of mortality in prematurity in a comprehensive manner. Their division of nurseries into separate units of infants, nurses and infants' supplies is a real contribution. The ultimate low in mortality of premature infants should be reached by such united efforts of the obstetric and pediatric services.

Dr. LEWIS A. KOCH, Brooklyn: We certainly feel that infection was one of the major causes of early mortality in past years, and its incidence has definitely been reduced. That is due not only to our better method of distributing our nursing load and care but, to some extent, also to the better treatment, antibiotic therapy and the like, which we now have available.

NEWBORN MORTALITY AND MORBIDITY WITH CONTINUOUS CAUDAL ANALGESIA

An Analysis of Cases in New York, Philadelphia and
Memphis, with Controls

Recognizing that the principles of prolonged narcosis in labor and general anesthesia for delivery are fundamentally dangerous for the baby, obstetricians in great numbers are filling the literature with reports of greater salvage of infants through management of labor and delivery with nerve conduction anesthesia through technics of local, pudendal and presacral block, spinal and continuous spinal, and saddleblock spinal anesthesia and caudal and continuous caudal analgesia.

Since 1942 there have been published two hundred and sixty-four papers in the medical literature recording results in more than 600,000 cases with continuous caudal analgesia used for the management of labor and delivery. Most of these reports have emphasized the well-being of the newborn infant who, with this technic, has escaped the penalty of transplacental narcosis from sedative drugs and general anesthetics.

In this report we have analyzed results in a significant number of deliveries from the U. S. Marine Hospital in New York, from the Philadelphia Lying-In Hospital

The Office of Health Statistics and Methods of the United States Public Health Service assisted in the statistical phases of this paper.
Read before the Section on Pediatrics at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

Because of lack of space this article has been abbreviated in THE JOURNAL. The complete paper will be found in the authors' reprints which the authors will be pleased to send on request.

From the Departments of Obstetrics of the U. S. Marine Hospital, Staten Island, N. Y., the Philadelphia Lying-In Hospital and the John Gaston Hospital, Memphis. Surgeons, United States Public Health Service (Drs. Hingson and Edwards) and Senior Assistant Surgeon, United States Public Health Service (Dr. Franklin).

and from the John Gaston Hospital in Memphis, Tenn. We have made a comparison in the latter two hospitals with control series managed with other forms of relief of pain. Coincidentally, in the John Gaston Hospital we have presented a series of 577 cases in which no form of drug therapy was administered for relief of pain either during labor or during delivery.

The New York report covering more than four years' work in the obstetrical department of the U. S. Marine Hospital on Staten Island is submitted as a model example of conservation of infant life where the regional methods of nerve block for delivery are used in 92.7 per cent of all cases. In this series of 1,687 cases there was 1 maternal death.

We have analyzed the combined stillbirth and neonatal mortality in these three hospitals, which data are presented in table 1.

Even though we were impressed with the total salvage of babies under the management of continuous caudal analgesia, certain dangers of the method have become apparent, and certain limitations from the obstetric point of view have presented themselves. These dangers and limitations in order of their significance are:

1. Primary intrauterine fetal anoxia as a result of the sometimes moderate to severe hypotension which develops in the mother from conduction nerve block of the vasomotor nerves. Whenever the maternal blood pressure remains below 80 mm. of mercury for several minutes during labor, the resting and contracting uterine tone is conceivably greater than the arterial pressure. Clinically we have determined that this fetal anoxia is demonstrable in almost every case in which this condition is allowed to exist for five minutes or longer.

Should this condition remain uncorrected it would result in an overwhelming fetal anoxia. For this reason whenever the regional methods of nerve block are used the safeguards of facilities for high oxygen inhalation, vasopressor drugs, intravenous fluids and knowledge of the institution of autotransfusion through elevation of the mother's lower extremities to right angles with the long body axis should be readily available. Baby life has been lost and will continue to be lost when these warnings go unheeded.

2. Arrested and prolonged labors as a result of too early administration of the analgesia before the processes of labor have become established, in desultory and false labors, and as a result of extension of the anesthetic levels through somatic segments higher than the sixth thoracic, and to prolonged dependent migration of the anesthetic solutions through the sieve-like openings of the anterior sacral foramina involving Frankenhäuser's ganglions. These latter two errors in judgment and technic block significant motor pathways and absolutely arrest or make ineffectual the processes of labor.

3. Increased incidence of occipitoposterior positions. In some series this incidence is almost doubled over that usually considered normal.

4. Increased incidence of operative deliveries with a diminution in the incidence of spontaneous expulsion of the fetus.

5. Occasional direct transplacental fetal hypersensitivity to the local anesthetic used, as has been reported by Irving and others¹ and Siever and Mousel.²

1. Irving, F. R.; Lippincott, C. A., and Meyer, F. C.: Continuous Caudal Anesthesia in Obstetrics: Demonstration of Catheter Technic for Administration, New York State J. Med. 43: 1023-1029, 1943.

2. Siever, J. M., and Mousel, L. H.: Continuous Caudal Anesthesia in Three Hundred Unselected Cases, J. A. M. A. 122: 424-426, 1943.

With these hazards constantly in mind, we have sought to supervise the labors and deliveries managed under this technic with careful surveillance of the mother and the infant.

Since our own series of cases so managed is the first and largest series managed with continuous caudal

Chart 1.—Stillbirths and neonatal deaths per thousand live births, studies in three cities.

analgesia, we have spent months in analyzing for the medical profession the effect of this technic on the fetal mortality in the hospitals reporting this study. We have divided this study into two main divisions in order to compare results from two geographic areas.

In the Philadelphia series 87.6 per cent of the mothers were white and 12.4 per cent were Negro, while in the Memphis series 82.1 per cent were Negro and 17.9 per cent were white. The combined study involves an analysis of 7,893 births in 5,059 of which the mothers were delivered under continuous caudal analgesia and in 2,834 under some other method.

THE PHILADELPHIA STUDY

In a statistical analysis previously published by two of us, we analyzed the results of the delivery with continuous caudal analgesia of 2,516 mothers as compared with a control group of 1,024 mothers delivered with the usual anesthetics and sedatives. All the deliveries took place at the Philadelphia Lying-In Unit of the

Chart 2.—Percentage of infants who required a special agent to induce respiration in the caudal and control groups.

Chart 3.—Percentage of infants who made a net gain in weight by the seventh day of life in the caudal and control groups.

Pennsylvania Hospital. In the control group 62 per cent of the mothers were delivered with nitrous oxide and ether, 30 per cent with nitrous oxide alone, 2 per cent with ether alone, 0.4 per cent with other anesthetics and 5.6 per cent without an anesthetic. Data about mothers in the two groups indicate that when

they came to delivery they were comparable with respect to age, parity, state of health and many other factors that might influence the outcome of childbirth. The following material is extracted from the Philadelphia report.³

The delay in respiration of the newborn infant and the necessity for a special agent to induce respiration may be indications of the effect on the infant of anesthetics given to the mother during labor. Table 2 shows the proportion of infants discharged alive from the hospital in whom respiration was delayed for more than two minutes or in whom special agents were used to induce respiration. Among those delivered by continuous caudal analgesia, the group of infants who had difficulty in breathing amounted to 3.6 per cent of the total, as compared with 9.6 per cent of the control group, a difference which is definitely significant. In the caudal group 2.5 per cent of the infants required the use of a special agent to induce respiration as compared with 8.7 per cent in the control group, a difference which is also definitely significant (chart 2). In the caudal group there were 143 premature⁵ infants

4. The fourfold table and chi square were used to test the statistical significance of the differences between the caudal and control groups with respect to the several measures that are expressed in rates or percentages.
5. Infants with birth weights of 5 pounds, 8 ounces (2,500 Gm.), or less, were classed as premature, in accordance with the standard adopted by the American Pediatric Society.

time of discharge from the hospital. Table 3 shows for the caudal and control groups the percentage of infants who had made a net gain of 1 or more ounces (28.3 Gm. or more) by the seventh day of life. Considering all infants, 11.9 per cent of those in the caudal group made such a net gain in weight in the first seven days of life, as compared with 9.2 per cent in the control group (chart 3). A difference of this magnitude is of doubtful or borderline significance in the statistical sense

per infant for the caudal group as compared with 3.39 ounces (96.1 Gm.) for the control group. For bottle-fed infants the corresponding average weights at birth were 7.02 pounds (3,175.71 Gm.) and 7.05 pounds (3,176.56 Gm.), respectively, and during the first week of life there was a net loss of 5.52 ounces (156.5 Gm.) per infant for the caudal group as compared with 5.77 ounces (163.6 Gm.) for the control group.

in that although probably real it may have been due to chance.

Table 4 and chart 4 show the distribution of the infants in the caudal and control groups according to weight at birth. The average weights at birth were 7.14 pounds (3,238.6 Gm.) for the caudal and 7.11 pounds (3,225 Gm.) for the control group, and the distributions of birth weights in the two groups were similar. In the caudal group the average weight at birth for infants who were breast fed was 7.21 pounds (3,270.4 Gm.) as compared with 7.30 pounds (3,311.2 Gm.) in the control group. During the first week of life there was a net loss of 3.75 ounces (106.3 Gm.)

Thus a higher percentage of infants in the caudal group showed a net gain during the first week of life, but, in terms of average ounces lost for all infants in the two categories, the differences between the caudal and control groups were small and not consistently in favor of either group.

Among infants in the caudal group, stillbirths amounted to 9.1 per thousand live births, as compared with 24.8 per thousand in the control group, a difference which is definitely significant (chart 5). Corresponding ratios for white stillbirths were 8.1 per thousand live births for the caudal and 23.4 per thousand for the control group; and for the few Negro still-

births, 16.1 per thousand live births for the caudal and 42.9 per thousand for the control group (table 5). The difference between caudal and control groups is statistically significant for white stillbirths, but in the small Negro groups even this large difference may have resulted from chance.

Since the infants were under observation only for the short time in the hospital and since the hospital stay varied for different mothers and infants, neonatal deaths were defined as those which occurred within the first week of life, practically all mothers being in the hospital for that minimum period.

Chart 5.—Stillbirths and neonatal mortality per thousand live births in the caudal and control groups.

Deaths in the first week of life in the caudal group amounted to 11.5 per thousand live births, as compared with 20.8 per thousand in the control group (chart 5). The corresponding figures in the white group were

Chart 6.—Stillbirths and neonatal mortality per thousand live births among mothers of different ages in the caudal and control groups.

9.0 per thousand live births for the caudal and 20.2 per thousand for the control group, and for the Negro, 29.0 per thousand live births for the caudal and 28.6 per thousand for the control group (table 5). A difference of such a magnitude as that between the rates for white infants in the caudal and control groups is

statistically significant, but the two rates for Negro infants are essentially the same. It may be noted that the mortality of the first week of life of 20.8 per thousand live births for all infants in the control group was approximately the same as that for the country as a whole—22.3, 20.8, 19.9 and 20.0 per thousand

Chart 7.—Neonatal mortality per thousand live births among full term and premature infants in the caudal and control groups.

live births for the years 1941, 1942, 1943 and 1944, respectively.

Taking into account both stillbirths and neonatal deaths, the total loss of infants amounted to 20.6 per thousand live births in the caudal group, as compared with 45.6 per thousand in the control group, a difference which is definitely significant (table 5). Among white infants the corresponding rates were 17.2 per thousand live births for the caudal and 43.7 per thousand for the control group, a difference which is also definitely significant. Among the Negro infants the corresponding rates were 45.2 per thousand live births in the caudal group and 71.4 per thousand in the control group. In the small group of Negro mothers, even this large difference between the rates for the caudal and control groups may have occurred by chance; that is, it is not statistically significant.

Chart 6 shows stillbirth and neonatal mortality in the caudal and control groups among infants of mothers of three age groups: under 25 years, 25 to 29 and 30 years and over. The higher stillbirth and neonatal mortality rates in the control group are consistent for all three age groups of mothers.

It is generally recognized that premature infants have a high neonatal mortality, but there are few data on actual death rates among premature as compared with

† Premature includes infants weighing 5 pounds, 8 ounces (2,500 Gm.) or less

full term infants. In this study there were 167 premature infants in the caudal group and 66 in the control. In the caudal group neonatal mortality was 132 per thousand premature live births, as compared with 227 per thousand in the control group (chart 7 and table 6). In this small group of premature infants, a difference of this magnitude or larger would occur by chance seven times in one hundred trials and cannot be considered as statistically significant. Among full term infants the neonatal mortality rates were 3.0 and

form of regional nerve block anesthesia was utilized in every case, so that there was no selection of a general anesthetic or of no anesthetic for any one particular case.

Table 7 and chart 8 show the distribution of infants in the caudal, spinal, general and no anesthesia groups according to weight at birth. The average weights at birth were 6.82 pounds (3,093.5 Gm.) for the caudal group, 6.80 pounds (3,084.4 Gm.) for the spinal, 6.81 pounds (3,089 Gm.) for the general and 6.66 pounds

6.4 per thousand full term births in the caudal and control groups, respectively, but this difference also is not statistically significant.

THE MEMPHIS STUDY

The Memphis Study is composed of 2,626 consecutive births of which 1,271 live and stillbirths were managed with continuous caudal analgesia, 324 were managed with spinal and continuous spinal analgesia, 375 cases were managed with general anesthesia and 577 cases with no form of anesthesia. In the latter group of cases the deliveries were either tumultuous and precipitate or they occurred at times when all available intern and residency supervision was utilized in the delivery of other patients. So far as possible some

(3,020.9 Gm.) for the group in which no anesthetic was used. When all babies weighing less than 3 pounds (1,306.8 Gm.) are excluded from the latter group, the average weight at birth was 6.83 pounds (3,098 Gm.). Since in many of the precipitate deliveries in the groups with no anesthesia the infants weighed less than 3 pounds with a poor chance of viability, no infants in this group weighing less than 3 pounds were considered in the comparison presented in chart 9.

Among all infants in the caudal group, stillbirths amounted to 18.4 per thousand live births. It will be noted that this rate is twice that of the Philadelphia study and is explained by the high percentage of Negro patients in this group who have shown a greatly increased stillbirth rate. Yet there were 56.3 stillbirths

per thousand live births in the general anesthesia group. This was more than twice the 24.8 stillbirths per thousand live births in the Philadelphia series delivered in the control group.

The stillbirth rate for deliveries under spinal anesthesia of 45.2 per thousand live births was also high. Possible reasons for this high rate are presented elsewhere in the paper. The stillbirth rate for deliveries under no anesthesia of 80.4 per thousand live births was alarming. It emphasizes the dangers of uncontrolled, tumultuous labor as a cause of intrauterine anoxia. Pressure trauma of rigid maternal musculature against the soft tissues of the infant (particularly the premature infant) is dangerous. The premature infant not only suffers from the anoxia of the tumultuous contractions of precipitate labor, but is not vigorous enough to withstand the rigidity of a mother's muscu-

lature of the birth canal and perineum when she, because of pain, is accentuating the traumas of birth through voluntary muscular straining with sometimes convulsive force (chart 10 and table 9). The high neonatal mortality of 63.6 per thousand live births in this group suggests irreparable trauma compared with the low neonatal mortalities of 18.4 and 16.9 in the caudal and general groups, respectively.

It should be pointed out that the general anesthesia group was comprised of mothers who came to the hospital late in labor and were so close to delivery that no time was available for the administration of a regional nerve block anesthetic. On the whole this group contained a larger number with uncomplicated labor and delivery than the other groups. Yet in the spinal anesthesia group the neonatal mortality was 29 per thousand live births and in the group with no anesthesia and with tumultuous labor the neonatal mortality was 34.9 per thousand live births even after all infants under 3 pounds in this latter group were excluded.

Because of the unexpected high combined stillbirth and neonatal mortality in the spinal anesthesia group of 74.2 per thousand live births, this group was exam-

Chart 9.—Neonatal mortality per thousand live births among full term and premature infants, Memphis study, 1946 (Negro and white infants, under one week).

Chart 11.—Stillbirths and neonatal mortality (under 1 week) per thousand live births among Negro and white mothers of different ages, Memphis study, 1946.

ined more minutely. It is seen in table 8 that in the full term infants this combined stillbirth and neonatal

mortality of 47.7 per thousand live births compared unfavorably with the 15.0 in the caudal group. Also in the premature group the combined stillbirth and neonatal mortality of 220 per thousand live premature infants compared unfavorably with the 174 in the caudal group.

The combined neonatal and stillbirth rate in the group with no anesthesia was 25.2 for full term infants and 377 for premature infants weighing 3 pounds or more at birth. These high rates make us seriously question the safety of those methods which withhold pain relief during labor and delivery. An evaluation of those methods which exclude the use of pain-relieving drugs and anesthetics should include not only an analysis of maternal mortality and morbidity, but also an analysis of results relating to stillbirths and neonatal mortality and morbidity. To date no such study has been reported.

This paper has been concerned with an analysis of fatalities in the first week of life in the various anesthetic groups. Such an analysis is only an apical index of the extensive morbidity which forms the base of the pyramid that comprises such a large part of pediatric practice.

Chart 11 and table 10 show stillbirth and neonatal mortality in the caudal, spinal and general anesthesia groups among mothers of the three age groups: under 25 years, 25 to 29 years and 30 years and over. The lower stillbirth and neonatal mortality rates in the caudal group are consistent for all three ages of mothers. Table 10 emphasizes the high loss of infant life both as stillbirths and neonatal deaths in the noncaudal groups.

In this paper we have presented the stillbirth and neonatal mortality rates in the various anesthetic groups. We are not drawing any further conclusions at this time.

ABSTRACT OF DISCUSSION

DR. JAMES G. HUGHES, Memphis, Tenn: The authors' figures in regard to early spontaneous onset of respiration and the diminished need for special agents to induce respiration are significant. They check with the common observation that "caudal babies" are usually more alert and wide awake when delivered. This improvement in respiratory function in the first moments of life is of great importance in all newborn infants, but it has particular significance in premature ones, notorious for their respiratory difficulties and carrying the highest mortality rates of any pediatric group. It is well to remember that the salvage of the premature infant is the core of the problem of reducing infant mortality rates. At the University of Tennessee, we have been interested in obtaining evidence on the functioning of the cerebral cortex in newborn infants. The pediatric department has been engaged in a study of electroencephalography of the newborn infant. Many of the tracings have been obtained in the first minutes of life. It appears from tracings taken on the newborn infants whose mothers were delivered under continuous caudal analgesia that there is a more rhythmic pattern to the tracings, and more superimposed fast activity, which may indicate a more alert cerebral cortex. The difficulty in interpreting these tracings lies in the fact that normal patterns have not been well established for the first few hours of life. We are especially interested in what differences may be detected in regard to cortical activity of children born of mothers given various types of sedation, general anesthesia, continuous caudal analgesia or no drugs at all. At present we

have no definite conclusions to report. The authors do well to give prominence to the hazards to the fetus inherent in the procedure of caudal analgesia. The drop in maternal blood pressure, which may occur to levels dangerously low for fetal safety, is of special importance. The increased incidence of occipitoposterior presentations and operative deliveries from below tend to increase fetal mortality. Therefore, good judgment and careful technic, especially in the use of forceps, must accompany such forms of pain relief, if good results are to be obtained. On the basis alone of early, spontaneous onset of respiration with decreased need for stimulant procedures and drugs, caudal analgesia is a real contribution to the reduction of the newborn death rate. The figures given by the authors showing lower rates of stillbirths and neonatal deaths are probably due, in large part, to this improvement in respiratory function. To reduce to an even lower level the stillbirth and neonatal death rates will require a medical profession more and more oriented toward affording every possible safeguard to the unborn child.

DR. JOSEPH B. SNEFFERY, Washington, D. C.: At Providence Hospital in Washington, D. C., we had over three thousand deliveries last year, and among those there were 214 premature babies. This is a small number in comparison with Dr. Hingson's thousands of deliveries, but it tells the same story, and every little bit adds up to further the cause of giving caudal analgesia especially in these premature babies. Statistical data are subject to much criticism, I suppose, but at least there are some constant factors in these. They are uncorrected, for one thing, and there are the constant factors. All these premature babies were cared for by three pediatricians in about equal proportion, and all the deliveries, or the vast majority of them at least, were normal deliveries. The only variable factor was in the group that received caudal analgesia and the group that received general anesthesia. In these two hundred and fourteen deliveries of premature babies, 89 per cent of the babies delivered with the mothers under caudal analgesia lived and only 72 per cent of these delivered with the mothers under general anesthesia lived. In the stillborn group, 4 per cent of the babies delivered with the mothers under caudal analgesia were stillborn, and 10 per cent were stillborn when general anesthesia was used; and of the babies who were born alive but died later, 7 per cent were delivered with the mothers under caudal and 18 per cent under general anesthesia. From all of these groups, it is seen that the figures definitely favor caudal analgesia. The theory that caudal anesthesia relaxes the pelvic floor, has no narcotizing effect on the baby, has been talked about before. These figures actually back it up. It certainly is a real indication, I believe, in premature babies. It gives them their one good chance.

DR. RUSSELL WILBUR ALLES, Detroit: Here we have been presented for the first time with statistical proof, based on an acceptably large number of cases, that labors conducted under continuous caudal analgesia offer the best prospects for the welfare of the baby. At the same time, the time-honored conviction that babies fare better when the mother has no pain relief during labor has been dealt a fatal blow, for the poorest results are here shown to occur in babies whose mothers had no method of pain relief applied during labor. In fairness to the other methods of pain relief, it should be noted that while the results were uniformly better with continuous caudal analgesia, the strikingly large infant mortality when no analgesia or anesthesia was used was responsible for a major part of the deterioration in this group. A reduction of almost one half in neonatal mortality and almost two thirds in stillbirth mortality must always be impressive. In prematurity, which contributes so generously to our infant mortality statistics, our aim as obstetricians is to conduct labor with a minimum of risk to the baby, and from the results here reported, it would seem that continuous caudal analgesia more nearly approaches that goal than any other method heretofore used. The authors have stated the objections to continuous caudal analgesia, and these objections are neither minor nor invalid. They serve to stress

the fact that continuous caudal analgesia is not a method to be carelessly used by those who are not well acquainted with its technic, use and risks. The attendant complications are such that they can be most safely overcome only by those who are thoroughly conversant with obstetric art and practice. The care and time consumed for its safe application will always be a major obstacle. The importance of this study is enhanced by the fact that the authors and their associates were in direct charge of all the cases in the study and therefore we can assume that the same standards of care prevailed in all cases.

DR. GEORGE J. ANDROS, Chicago: I am asked frequently whether I can name any particular case in which general anesthesia has been the direct cause of fetal mortality. It often becomes extremely difficult to pick out such cases, but in what we have heard this afternoon we appear to have the answer. At the Chicago Lying-in Hospital in the past five and a half months we have used an allied technic of pain relief, saddle block spinal anesthesia, in over 1,000 cases. In analyzing the first 719 cases, we noted that only 6 of these women went home without a live baby. In 3 instances, the fetus was known to be dead before the saddle block was administered, and this was proved by the condition of the baby after delivery. Here the regional method was used for the benefit of the mother. The remaining 3 infants breathed spontaneously immediately after birth and died in the neonatal period. Causes of death revealed by autopsy were resorption atelectasis and jaundice in a 30 week premature infant, a major congenital abnormality and pneumonia. These figures give us an uncorrected fetal mortality rate of 0.85 per cent, and a corrected rate of 0.42 per cent. A somewhat comparable control series at the Chicago Lying-in Hospital shows less than 2 per cent fetal mortality. Probably Dr. Hingson would say that a sudden fall of blood pressure was a factor in the high fetal mortality in his group in which spinal anesthesia was used, which I know was not saddle block. Ninety-four per cent of our levels of anesthesia were at the ninth or tenth thoracic segment, and another 3 per cent at the eighth. There is not much fall in blood pressure with these levels. Five patients had levels to thoracic 5. Eighty-six per cent of our patients had a fall in systolic blood pressure of less than 30 mm. of mercury; 72 per cent had less than a 20 mm. drop. Seventy per cent of these patients needed no treatment, and the rest responded readily to oxygen and/or vasopressor drugs. In only 11 of our 719 cases was there a transient fetal heart rate drop to below 100 per minute, in association with significant fall in blood pressure.

DR. HAROLD W. ADAMS, Somersworth, N. H.: An evaluation of any method of controlling the pain of childbirth must carefully consider the health and vitality of the baby along with the health and comfort of the laboring mother. At Frisbie Memorial Hospital in Rochester, N. H., 736 infants have been delivered under continuous caudal management since Jan. 1, 1944, as compared with the 1,372 births under other forms of management over the same period of time. From this total of 2,108 births, we believe that the percentage of live births with the mothers under caudal analgesia compares favorably with the percentage of live births under other forms of management combined. Of the group of 736 caudal births, there have been 11 stillbirths, or a caudal stillbirth percentage of 1.49. In this group, there were also 8 neonatal deaths, giving a combined stillbirth-neonatal mortality of 2.6 per cent. Incidentally, of the 11 stillbirths reported, there were 6 macerated babies whose deaths were presumed for sometime before the onset of labor, 3 stillbirths from difficult labors with malpositions in midforceps deliveries, 1 spina bifida and 1 anencephalus. All eight neonatal deaths took place within the first four postnatal days, 1 infant weighing 27 ounces (765.4 Gm.) and living 26 hours, 5 others being premature and weighing less than 4 pounds (1,814.4 Gm.), and 2 deaths were not attributed to birth management. Of the control group of 1,372 births, there were 31 stillbirths, or a stillbirth percentage of 2.26, as compared to 1.49 per cent of the caudal group. I regret that an incomplete record of neonatal deaths in the control group will not permit me to give an accurate comparison of deaths of the newborn. However, I do

know that our combined stillbirth-neonatal percentage of 2.6 is well below the combined national figures of 6.8 per cent for all races and 4.8 per cent for the white race. In our series of caudal births, we have been greatly impressed with the condition of the newborn. The average infant breathes almost immediately, and rarely does one require resuscitation or special agents to stimulate respiration. We have not found this to be true of babies born to heavily sedated mothers or mothers under general anesthesia.

DR. ROBERT A. HINGSON, Memphis, Tenn.: Certainly, the electroencephalographic studies begun by Dr. Hughes in Memphis on the immediate postnatal reactions of the infants delivered with the various anesthetic agents should be continued, because in such basic experimental pediatrics we can get a clue to the altered physiology in the newborn infant which may seriously influence the developing baby in the first few days of life. We welcome the active consultation of the pediatrician. Dr. Andros has presented an excellent initial report concerning the use of saddle block spinal anesthesia in the Chicago Lying-in Hospital. The principles of caudal and saddle block spinal anesthesia are the same from the standpoint of the baby, the obstetrician and the pediatrician. Only the anesthesiologist and the mother are confronted with different experiences and different principles of technic with continuous caudal and saddle block spinal anesthesia. We favor the advancement of all forms of regional nerve block because we have clearly demonstrated that all forms of regional nerve block produce a reduction in infant mortality, when compared with control groups managed with systemic narcosis and general anesthesia and no anesthesia. Therefore, we are pleased to join those who have done pioneer work in different technics. We encourage the skilful use of conduction, nerve block technics in obstetrics. Such use will produce the salvage of the baby that has been demonstrated here. Dr. Alles in Detroit, Dr. Sheffery in Washington, Dr. Andros in Chicago and Dr. Adams in New Hampshire have proved that the advantages of continuous caudal analgesia in infant conservation are not geographic. The first hundred years of history of the American Medical Association have produced a startling reduction in maternal mortality. One hundred years ago, we lost more than 60 mothers per thousand live births. Today, we lose 2.1 mothers per thousand live births. It is my plea that the second hundred years of achievement of the American Medical Association be devoted to the salvage of the baby, since, as it now stands, an over-all loss of 6.8 per cent of our infants is entirely too high. We have demonstrated to you the bridge that will take us across the chasm of infant deaths to a reduction of infant mortality and to a healthier group of young Americans.

A Great Moral Struggle.—When Elizabeth Blackwell conceived the idea of becoming a doctor of medicine, there was no means in America or Great Britain by which a woman could receive a medical education. Single-handedly, however, she undertook to remove this barrier to the advancement of women. The thought of studying medicine first came to her attention through the illness of a friend, but before long the idea took on in her mind a moral aspect. "The idea of winning a doctor's degree," she writes, "gradually assumed the aspect of a great moral struggle, and the moral fight possessed immense attraction for me." It is this sense of being a standard bearer of a righteous cause, of consecrating oneself to the service of humanity, which characterizes the earlier generations of women doctors. In 1845 Elizabeth Blackwell decided to study medicine. After being rebuffed in Philadelphia and New York, she finally gained admission to Geneva Medical College, from which she received her medical degree in 1849. In 1869 she returned to England and settled in London. Dr. Blackwell died in 1910. Her autobiography, "Pioneer Work in Opening the Medical Profession to Women—Autobiographical Sketches" (1895), is an outstanding human document.—Rosen, George, and Caspari-Rosen, Beate: 400 Years of a Doctor's Life. Cerebral schistosomiasis is rare and few operative cases have been reported in the literature. Bayoumi¹ stated that Tsunoda and Schimamura² were the first to find *Schistosoma japonicum* eggs in the brain. Manson³ noted the occasional occurrence of eggs of *Schistosoma haematobium* in the brain and spinal cord. Faust and Meleney⁴ stated that Yamagiwa in 1890 mentioned the occurrence of jacksonian epilepsy in a patient with schistosomiasis japonica and that Houghton in 1910 also described a case in which he suspected that symptoms referable to the brain were due to the deposit of *S. japonicum* eggs. They indicated that such cases are rare. Spiridion⁵ in 1936 described an outbreak of schistosomiasis japonica in China. Only three patients showed neurologic involvement. Egan⁶ in 1936 reported 2 neurologic cases of schistosomiasis japonica in a series of 12 English sailors who went swimming in the Yangtze river near Chinkiang, China. Edgar⁷ in the same year reported 1 case of epilepsy due to the infection of *S. japonicum*. Hoff and Shaby⁸ in 1939 reported 1 case of myelitis with mental confusion due to *S. haematobium* and referred to 3 cases of mental confusion associated with bilharziasis. Vitug and Cruz⁹ in 1941 reported 2 cases of schistosomiasis japonica involving the brain in the Philippines. They stated that schistosomiasis japonica is endemic in certain regions in the Philippines; namely, Leyte, Samar, Sorsogon, Surigao and Mindoro. All patients coming from these places to the Philippine General Hospital, whether they manifest symptoms of the disease or not, almost invariably show eggs of *S. japonicum* in the

stools, but cerebral schistosomiasis in the Philippines is a rare phenomenon. In the Philippine medical literature there are only two reports before Vitug's referring to schistosomiasis of the brain. Nieva¹⁰ reported a patient with probable diagnosis of schistosomiasis of the brain, and Africa¹¹ made passing mention of finding post mortem the eggs in the brain as well as in the other viscera in a fatal case of schistosomiasis.

Carroll¹² has reviewed the literature of schistosomiasis of the brain up to January 1946. He found 8 cases and added 4 new ones.^{12a} Of the 8 previously reported, 2 were proved to be schistosomiasis after an exploratory craniotomy for tumor of the brain.¹³ Autopsy was done in 1 other case.⁹ The diagnosis in the remainder of these cases and in those of Carroll was based on a history of exposure to *Schistosoma*, observation of *Schistosoma* eggs in the feces and the clinical picture. All of Carroll's cases occurred in American troops on Leyte, apparently in good health without exposure to this illness previous to the American invasion of the island late in 1944. In all except 1 case, the neurologic manifestations took place during the acute stage of the disease.

Tillman¹⁴ has recently (January 1947) reported 6 new cases of schistosomiasis japonica with cerebral manifestations among the American troops on the Island of Leyte.^{12a} There were 6 cases among 181 patients with schistosomiasis admitted to his hospital from January 15 to July 15, 1945. An additional patient observed at another hospital on Leyte was included in his report. All 6 patients were treated both with stibophen ("fuadin") and potassium antimony tartrate before they were sent back to the United States. Clinical symptoms were consistently improved after the treatment, although the parasites were not completely eradicated during the short period of observation. Cerebral schistosomiasis may sometimes appear clinically several months or even several years after the primary invasion by the cercariae. Consequently, one would expect to see a certain number of cases of cerebral

* Formerly captain, Medical Corps, Army of the United States.

Lieut. Col. Joseph M. Cameron, Medical Corps, United States Army, gave us permission to present the 2 cases which he observed and treated by craniotomies. Professor Ernest Carroll Faust, acting head of the Department of Tropical Medicine, Tulane University, provided in a personal communication comments regarding the pathogenesis, diagnosis and treatment of schistosomiasis. Dr. George M. Saunders, assistant professor of preventive medicine, University of St. Louis, permitted us to include his report. J. Palmer, Medical Corps, United States Army, made the pathologic report in case 2, and Col. Raymond O. Dart, Medical Corps, United States Army, Director of Army Institute of Pathology and Army Museum, furnished the photomicrographs. Mr. Lew Sunny, of Walter Reed General Hospital, photographer for the laboratory, made the photographs for case 1. Col. Raymond O. Dart and Col. J. E. Ash, Medical Corps, United States Army, of the Army Institute of Pathology, Washington, D. C., supplied the captions for figures 5, 6 and 7.

12a. The number of cases reported by Thomas and Gage,²⁰ Carroll,¹² Tillman,¹⁴ and Billings, Winkenwerder and Hunnien (table 1) are corrected in this paper to avoid duplication on the basis of a personal communication from Billings who had access to all these manuscripts when he wrote on schistosomiasis japonica for the Surgeon General's History of the Medical Department in World War II. The following data is so far as can possibly be ascertained correct. The patients mentioned by Thomas and Gage, *Bull. U. S. Army IV*, No. 2, 1945 were three in number. Two of these cases were used by either Winkenwerder and myself or Tillman. They could therefore be deleted in a total count for convenience sake. The third was never proven to be a case of cerebral schistosomiasis so far as I know. The patient died and examination of the brain was thorough and no ova were demonstrated microscopically. Winkenwerder and I mentioned 7 cases of *S. japonica* involving the central nervous system. One of these was previously described by Thomas and Gage and another was used by Carroll. One was used only by us. The other 4 patients do not seem definitely to be in the group of proven or even symptomatic or clinical cases of cerebral schistosomiasis. Two complained of paresthesias, one had a peroneal nerve palsy, and the 4th had subjective transient impairment of the vision of the left temporal field, but no objective findings could be found, and when we saw him he had no central nervous system signs or symptoms. Carroll described 4 new cases, and one which was described by Winkenwerder and myself. Tillman described 6 new cases and one which had been previously described by Thomas and Gage. Thus in tabulating the separate cases one finds:

Thomas and Gage.....	2
Billings and Winkenwerder.....	2
Carroll.....	4
Tillman.....	6

Total..... 14 "

schistosomiasis among those who returned to the United States from endemic regions of schistosomiasis in the Pacific combat area.

Schistosomiasis of the brain should be considered in obscure diagnostic problems, including epileptiform convulsions and other neurologic diseases suggesting encephalitis or multiple sclerosis, especially if the patient is a soldier who has returned to the United States from an area in which schistosomiasis is endemic.

Experiences in World War II suggest that the disease is far more common than previously suspected and that a number of these cases may appear in the United States. We have been able to find references to 23 cases of cerebral schistosomiasis occurring during the fifty-six year period between 1890 and January 1946. During the fifteen month period following January 1946 we have been able to find published references to 16 additional cases. There is ample reason to believe that many other cases have gone unrecognized or have not been reported. All the reported cases are summarized in table 1.

It can be seen from table 1 that the diagnosis in 28 of these cases was presumptive, based on the association of neurologic manifestations with classic intestinal schistosomiasis. Prior to this report there were 10 cases in which the diagnosis was based on the discovery of *Schistosoma* eggs in brain tissue; 5 from biopsy and 5 from autopsy. Bayoumi¹ stated that *S. haematobium* is more apt to affect the spinal cord than the brain, being present in 3 cases out of 5 of bilharzial myelitis. Infection of the central nervous system with *Schistosoma mansoni* was reported by Muller and Stender.¹⁵ We found no reference in the literature to the presence of *S. mansoni* eggs in the brain, nor did we find any report of *S. japonicum* eggs occurring in the spinal cord. Among the total of 38 reported cases of cerebral schistosomiasis only 3 were due to *S. haematobium*, while the remaining 35 cases were due to *S. japonicum*.

In the Army General Hospitals, we have recently encountered 2 instances of cerebral granuloma caused by *S. japonicum* which we feel are worth reporting.

REPORT OF CASES

CASE 1.—The patient, a white man aged 26, with fourteen months' South Pacific duty, including service on Leyte, was well until the beginning of his present illness in August 1945. His symptoms at that time were low grade, persistent fever and weakness of the right arm and right leg. From the onset of these symptoms until August 13 the weakness of his right leg became progressively greater, so that on admission he was unable to walk.

On August 13 he had a jacksonian seizure involving the right side of the body without loss of consciousness. Examination at that time showed a right-sided hemiparesis with diminished sensation over the entire right side of the body, with generalized hyperreflexia and extensor plantar response on the right. There was slight weakness of the right facial nerve. At the time of the original episode, there was dysphagia and a blurring of vision together with the symptoms listed. Spinal puncture at that time showed 15 lymphocytes and slight increase in globulin.

On September 7 he was evacuated to McCloskey General Hospital, where some improvement was noted in the strength of his right side, but the patient was having fairly severe generalized headaches. Examination showed paresis of the right arm and leg, with more involvement of the leg. Sensory examination revealed hyperesthesia, grade II, involving the

right arm and leg. There was mild hyperreflexia without any abnormal reflexes. Laboratory examinations at McCloskey showed that roentgenograms of the chest and skull were normal. Results of urinalysis, serologic tests, blood cell count and coccidioidin cutaneous tests were not significant. Spinal puncture on September 19 revealed no abnormality except for 62 white blood cells, but on a later date the number of lymphocytes had been reduced to 9. The course, while at McCloskey, was one of improvement, both symptomatically and in laboratory examinations. Before he left McCloskey the patient's weakness and dysphagia had improved. Psychometric examination showed only a mild decrease of mental function.

The patient was closely followed from the time of his admission at McCloskey General Hospital, and the clinical picture presented on his arrival at that hospital suggested that the probable basis for the patient's illness was either an expanding lesion or a vascular accident.

Following a complete work-up with a more careful and detailed analysis of his clinical records, however, it was felt that the most likely pathologic process was in the nature of

* Caused by *Schistosoma haematobium*.

† Duplications found by Billings are omitted.

a chronic inflammatory condition of a granulomatous type. This would more readily explain the persistent pleocytosis with the accompanying low grade fever and leukocytosis noted during the early phase of his illness.

With this in mind, the various specific and nonspecific granulomatous lesions were considered and the diagnostic approach was accordingly altered. Special laboratory procedures on the spinal fluid and cutaneous tests together with roentgenograms of the chest ruled out fairly well the possibility of a syphilitic or tuberculous condition, and it was felt that a most likely etiologic factor responsible for this chronic localized encephalitic process was in the nature of a fungus, probably coccidioidomycosis, or a parasitic infection such as toxoplasmosis or histoplasmosis.

A pneumoencephalogram was considered but, because the patient continued to improve considerably in the several months of his hospitalization at McCloskey, it was felt that he should be treated more conservatively, and he was transferred to Brooke General Hospital for further observation and treatment, with the diagnosis of chronic focalizing encephalitis, cause and type undetermined. The patient was seen in April 1946, and it was noted that a considerable improvement of his hemiparesis and hemihyperesthesia had been made, but there was a complete motor aphasia which had developed in the course of six weeks'

15. Muller, H. R., and Stender, A.: Bilharziose des Rückenmarkes unter dem Bilde einer Myelitis dorso-lumbalis transversa completa, Arch. f. Schiffs- u. Tropen-Hyg. 34: 527-538, 1930; cited by Speigel.²⁰

time, with the onset in February 1946. There was no evidence of any sensory aphasia and the patient could write and copy well, although there was complete inability to express himself verbally. Laboratory studies at this time showed serologic reactions to be negative. The urine was entirely normal. The white blood cell count was 12,000, with 12 per cent eosinophils. The spinal fluid was essentially normal except for increased lymphocytes up to 14. Necator americanus, on one occasion, was found in the stool, and it was felt that this explained his eosinophilia. However, after treatment with hexylresorcinol, the eosinophilia persisted.

The fact that the initial hemiplegia had cleared so well, to be followed subsequently in a period of six months by progressive aphasia with a persistent pleocytosis, indicated renewed activity with good localization in the left frontoparietal region. This further substantiated the fact that the pathologic process was probably of a chronic inflammatory nature of a granulomatous type. The patient was followed closely, and in April 1946 the neurologic examination remained essentially the same except for examination of the fundus, which showed a venous engorgement and haziness of the disks bilaterally. This fact, together with the excellent localization, indicated clinically that, regardless of the etiology, it must be considered as an expanding lesion, and for this reason it was deemed advisable to transfer the patient to the Neurosurgical Service for an air study. Encephalographic studies of the brain revealed a fair amount of air in the right lateral and third ventricles. Only a minimal amount of air was seen within the posterior horn of the left lateral ventricle. The right lateral ventricle was moderately dilated and appeared to be displaced to the right. The anteroposterior view showed no evidence of air in the left lateral ventricle. The roentgen observations were consistent with a tumor in the temporoparietal region of the left hemisphere. A craniotomy was performed on April 12 by means of a left frontoparietal flap. When the dura was exposed, it was found to be under only moderate tension and adherent at only one point in the frontal region to the underlying cortex. The gyri were decidedly flattened and the sulci obliterated.

Fig. 1.—Many sections exhibited ova, pink-staining bodies characteristic of *S. japonicum* eggs, surrounded by an intense inflammatory cell reaction, necrosis and fibrosis. X 100. (Photomicrograph by Mr. L. Sunny, Walter Reed General Hospital.)

The dura was adherent to the posterior portion of the third middle frontal convolution. After the area was exposed the inferior frontal convolution, though not adherent, bore the same gross appearance. It was harder than its neighbors, yellow in color, less vascular on the surface and was studded with nodules ranging from pinpoint size to 2 mm. in diameter. These

were hemispherical elevations resembling pimples, such as might be found on the skin. Biopsies were taken to include some of these, as far away as possible from the motor speech area. Inasmuch as frozen section biopsy was indeterminate as to the type of tissue causing the tumor mass, the bone flap was removed and the scalp closed as a large decompression. Immediately after the operation the patient's progress was not significant, but

Fig. 2.—Often the eggs appeared together in clumps. X 100. (Photomicrograph by Mr. L. Sunny, Walter Reed General Hospital.)

on the fourth postoperative day the movements of the right hand and his speech were improved. However, the patient had two jacksonian convulsions. On April 18 he was started on stibophen, 1.5 cc. intramuscularly, followed the next day by 3.5 cc. and thereafter by twelve daily doses of 5 cc. each. On May 6 the patient had another jacksonian seizure, following which there was paralysis of the right arm, lasting approximately eight hours. On May 20 a similar course of stibophen was started.

The patient continued to improve very slowly. Throughout his hospital stay exhaustive search for *S. japonicum* failed to show any evidence of the parasites or eggs in any specimens except that of the biopsy of the brain. A follow-up encephalogram was performed July 3, and it was noted that there was definite improvement as compared with the preoperative picture, taken in April. There was only slight dilatation of the posterior portion of the body of the left lateral ventricle with slight shifting of the ventricular system to the left. The patient received three courses of stibophen in all and underwent an intensive regimen of physical therapy for the hemiparesis, which improved considerably. He also received speech training, and this has likewise shown a slow but gradually progressive improvement. The last residuum on May 20, 1947 was a minimal aphasia; however, the patient was able to carry on a slow conversation.

Pathologic Changes Noted at Biopsy.—Gross Pathology: Numerous fragments of tissue were submitted. One consisted of a small grayish white, slightly indurated piece of tissue measuring about 1 by 8 by 6 mm. The remainder were numerous small grayish white slightly firm fragments of tissue measuring 1.5 cm. in total breadth. A small piece of dura measuring 2 by 1.3 cm. was also submitted.

Microscopic Examination (figs. 1, 2 and 3): On microscopic examination, the most striking feature observed was the presence of numerous oval-shaped, pink-staining bodies occurring in almost all the fragments. These were characterized by round ends. They had a peripheral shell-like capsule, from many of which there protruded numerous pink-staining small

necrotic cells. The inner aspect of these pink-staining bodies was occupied by numerous blue-staining granules varying in size and shape. These oval-shaped, pink-staining bodies had the characteristic appearance of *Schistosoma* eggs. They were surrounded by an intense inflammatory reaction consisting of many eosinophils and some neutrophils. In the vicinity immediately surrounding these areas there was, in addition to the inflammatory reaction, considerable necrosis. There were numerous other areas in which these eggs may or may not have been present, characterized by extensive necrosis surrounded by dense fibrosis. Occasional giant cells were seen in these areas. The fibrotic zone was usually surrounded by a moderate infiltration of round cells and polymorphonuclear cells, among which were seen a fair number of eosinophils. There were many vessels showing decided perivascular cuffing of round cells associated with a few polymorphonuclear cells. The brain substance exhibited pronounced hemorrhage, degeneration and gliosis.

The oval-shaped bodies found in the brain lesion were characteristic of the eggs of *S. japonicum*.

CASE 2.—The patient was a white technician fifth grade, aged 22, with seventeen months' service on Leyte and Okinawa, who was admitted to the Percy Jones General Hospital on Dec. 22, 1946 with the chief complaints of two attacks of unconsciousness preceded by left-sided twitching and also several episodes of twitching of the left leg or left arm not accompanied by unconsciousness. The present illness started on November 6 as a sudden onset of numbness in his left knee, traveling to his left leg, while at the same time the patient experienced twitching sensation of the left extremities. In the first attack he lost consciousness; since then he had several attacks of similar nature but syncope supervened in only one. The later attacks then occurred on the right side, and his symptoms were then limited entirely to this side of the body. The patient stated that he had no aura of the attacks and that the first he was aware of them was a twitching of the extremity. On Feb. 13, 1947 the patient had a seizure which at the time when he was first seen manifested itself in rather rapid, coarse motions of the right leg, consisting of flexion and

and it was noted that while he was exerting force the contractions of the right leg became less rhythmic and less rapid. The patient did not at any time lose consciousness; he was alert and responded well to questioning. His extraocular movements were entirely normal. The pupils were equal and were not dilated. The entire seizure lasted for approximately three minutes.

Fig. 4.—Notice the small nodules on the gyri.

Past history and family history were of no importance except for the fact that he had several attacks of headaches which were intense. There was no history of serious injuries. The patient could not recall having had any symptoms and signs relative to an acute phase of schistosomiasis before the present illness. He was well adjusted socially and had no emotional disturbances or personality maladjustment.

On examination between seizures, it was noted that there was impaired control of the right arm and leg, which the patient stated had been present since the last attack, on February 13. There was a questionable Babinski reflex on the right side; however, true fanning was obtained only twice, but at no time was there actual plantar flexion, as was elicited on the left. There was a definite ankle clonus which was transient. There was definite adiadochokinesis on the right and when the patient's eyes were closed there was decided swaying to the right and down. However, the results of the finger to nose test were within normal limits. The patient had no difficulty in identifying objects with the right hand. The heel to knee test elicited a positive result on the right. The Romberg sign was positive, and the patient fell to the right. He also walked with a broad base, this being effected by adduction of the right leg on walking.

On fundusoscopic examination there was possibly minimal increased tortuosity of the vessels, and if there was papilledema it was minimal.

The patient had had two pneumoencephalograms, and both showed normal arachnoid space filling, but on neither was there filling of the ventricles. The lesion was diagnosed by ventriculogram as a space-occupying mass in the left parietal region, with distortion and displacement of the lateral ventricle to the right side, exact etiology undetermined. Among the possibilities were meningioma, glioma, hemangioma and schistosomiasis. Preoperatively the surgeon made a presumptive diagnosis of cerebral schistosomiasis, basing it on the clinical picture in addition to seventeen months' overseas duty in the South Pacific and an eosinophilia of 6 to 8 per cent, as well as on the general clinical resemblance to case 1.

Fig. 3.—Eggs, inflammatory cell reaction and necrosis were observed on the meningeal surfaces. $\times 100$. (Photomicrograph by Mr. L. Sunny, Walter Reed General Hospital.)

extension, abduction and adduction and flexion and extension of the foot. This soon diminished to a contraction limited almost entirely to the adductors which was not rhythmic or rapid. The clonus of the right foot was more pronounced than at the previous examination. There was definitely some spasm of the leg and to a lesser degree of the right arm. After this the patient was asked to squeeze the hand of the examiner,

Laboratory Data.—Roentgenograms of chest and skull were normal. Parasites were not found in stool. The urine was normal. There were 5,060,000 red blood cells and 5,550 white blood cells, with 56 per cent neutrophils, 36 per cent lymphocytes, 1 per cent monocytes, 6 per cent eosinophils and 1 per cent basophils. The hemoglobin was 29 per cent. Total protein in the cerebrospinal fluid was 26 to 13 γ . An examination of the ventricular fluid was made on Feb. 18, 1947. The fluid was cloudy. There were 8,300 red blood cells and 30 white blood cells, with 7 polymorphonuclear cells and 2 lymphocytes. There was no globulin.

On February 25 craniotomy was performed by means of a frontoparietal flap on the left side. A flap incision was made in the dura, which was reflected medial. When the dura was reflected, the posterior portion was found adherent to the cortex, and after resection many small, yellowish white masses were discovered, measuring approximately 2.5 mm. in diameter (fig. 4). The diagnosis of the lesion was schistosomiasis and was confirmed by frozen section. The mass was removed. Hemostasis was then carried out. There was bulging of the brain substance. The dura was not closed. The bone flap was removed.

The patient was stuporous after the operation and exhibited aphasia. Spinal tap was done in March with an initial pressure of 160 mm., which was reduced to 115 mm. Another spinal tap on March 4 revealed an initial pressure of 260 mm., which was reduced to 130 mm. The patient improved steadily. By March 23 the hemiparesis had so diminished that only

Fig. 5.—An old granuloma of the brain containing ova of *Schistosoma*, the majority of which are necrotic; the dark ones are calcified, but cell structure is still evident in several. Active inflammatory reaction has been replaced by dense hyalinized connective tissue.

minimal weakness remained and the aphasia had diminished so that the patient could carry on reasonably good conversation. On March 19 he was placed on a course of stibophen, administered in doses of 1.5 cc. intramuscularly for two consecutive days with omission on the third, to be continued according to the routine of medical treatment.

Examination on May 20 revealed no neurologic deficit or aphasia.

Pathologic Report.—The specimen was a segment of cerebral cortex (craniotomy).

Gross Examination: Material submitted consisted of an excised segment of cerebral cortex, with arachnoid, measuring 2.5 cm. in diameter and 0.5 to 0.8 cm. in thickness.

Fig. 6.—Higher power view of the group of ova shown in figure 5. The ova are deteriorated—one partially calcified. Foreign body giant cells and a few epithelioid cells and lymphocytes are evident.

Microscopic Examination (figs. 5, 6 and 7): Sections revealed in the superficial portion of the excised cortex numerous pseudotubercles measuring up to 0.25 cm. in greatest dimension. In the central portion of these pseudotubercles were nests of eggs of *S. japonicum*, about which there was a decided foreign body giant cell reaction. These giant cells were large, irregular in outline, with eosinophilic cytoplasm, and many individual giant cells contained 100 or more nuclei. The eggs and the associated giant cells were walled off from adjacent tissue by dense collagenous fibrous tissue. About the periphery of these pseudotubercles there was a zone of diffuse infiltration with inflammatory cells, for the most part lymphocytes.

Diagnosis: The diagnosis was schistosomiasis of the brain due to eggs of *S. japonicum*.

Recently, Saunders¹⁶ reported 2 additional cases of cerebral schistosomiasis, both in veterans of service in the Philippines. Through personal communication with one of us (T. H. C.) he has permitted us to include his 2 cases in our present report. A résumé of these 2 cases was given by Dr. Saunders as follows:

CASE 3.—R. J., a white man aged 27, entered Barnes Hospital, St. Louis, on May 2, 1946. He had been infected with *S. japonicum* while serving on Leyte during 1944. Apparently, however, the infection was not recognized at that time and

16. Saunders, G. M.: Personal communication to the author.

He was given simple "worm" medicine, after which his stool was said to be negative for eggs. He continued to suffer malaise and loss of weight. On Nov. 1, 1945, he was discharged from the army. In December of 1945 he began to notice that he had dizzy spells and felt sleepy. He had a feeling of falling to the right or forward. Headaches soon appeared, and by February 1946 these were accompanied by vomiting. He suffered some motor disability with his right leg. He sought the advice of a local physician because of headaches, and it was found that he had papilledema. He was referred to a neurosurgeon.

On admission to Barnes Hospital it was found that he had diminished visual acuity (right 10/30, left 10/20) with some haziness of the margins of the right disk. A ventriculogram made on May 6 showed that the right ventricle was pushed far to the left. A decompression operation was done and a tumor mass, granular in appearance, was found in the right cerebral hemisphere. This was removed and found to consist of granulomatous reaction around numerous eggs of *S. japonicum*. Postoperatively he did fairly well, but stools showed the presence of *Schistosoma* eggs. He was treated with stibophen and they disappeared.

The patient was seen in February 1947, when he complained of continuing headaches which kept him from working. However, he had no weakness or motor difficulty, although *Schistosoma* eggs have been found and he has had more treatment with stibophen at one of the Veterans Administration installations.

Fig. 7.—Another granuloma from the same case as in figures 5 and 6. Necrotic ova are surrounded by giant cells and epithelioid cells. These in turn are imbedded in dense hyalinized matrix about which there is moderate chronic inflammatory reaction.

CASE 4.—E. C., a white male veteran aged 38, was admitted to the Veterans Hospital May 14, 1946. Past history is incomplete but indicates that he served in the army for eighteen months in the South Pacific area. On April 20, 1946, he experienced dizziness and flashes of red light before his eyes. Four days later his right arm became paralyzed and his legs

partially paralyzed. He was admitted to the hospital with a diagnosis of left hemiplegia. Visual fields were found to be constricted and roentgenogram of the skull showed evidence of increased intracranial pressure. No papilledema was noted. There was noticeable muscular weakness of the extremities on the left. Lumbar puncture revealed that spinal fluid was under increased pressure. A subsequent note made two days later stated that fundusoscopic examination revealed papilledema of 3 D. bilaterally, and perimetry revealed homonymous hemianopsia on the left. Encephalograms showed incomplete filling of the left lateral ventricle.

On July 11 craniotomy was done, which revealed a deep-seated tumor in the left hemisphere. This was found to be partially adherent to the dura at the base of the middle cranial fossa. This mass was excised and found to contain eggs of *Schistosoma*. The patient had a stormy postoperative course. He was treated with several courses of stibophen. Observation after several months showed some residual paralysis with a moderate motor aphasia.

COMMENT

Schistosoma is classified under the phylum Platyhelminthes (flat worms), class Trematoda (flukes). There are three principal species which are pathogenic for men: (1) *S. haematobium* (causing Egyptian or urinary schistosomiasis); found almost exclusively in Africa; (2) *S. mansoni* (causing Manson's intestinal schistosomiasis), prevalent in Africa, the West Indies and Northern South America, and (3) *S. japonicum* (Asiatic schistosomiasis), with foci in Japan, Formosa, China, the Philippines, Celebes and reportedly also in Burma along the Chinese border. The lesions in our 2 cases were produced by eggs of *S. japonicum*, as the morphology of egg species is diagnostic.

Ash and Spitz¹⁷ in their "Pathology of Tropical Diseases" stated that "the deposition of ova rather than the intra-vascular presence of the adult worms accounts for the great majority of clinical symptoms and the pathological lesions in schistosomiasis. *Schistosoma japonicum* infection is by far the most acute and severe, the daily output of eggs for each worm being 50-300; *S. haematobium* infection is moderately severe as a result of a daily output of 20-30 eggs; *S. mansoni* infection runs the mildest course with 1-4 eggs daily." Faust¹⁸ questioned the validity of the statements about egg production per day for the three species of worms. He observed: "It would be much more accurate to state that at any one time the number of eggs in utero is the figure that Ash and Spitz have given. However, this does not necessarily mean that there is only one uterine filling with eggs per day."

The distinction of eggs of these three species of *Schistosoma* is well known: The *S. mansoni* egg has a prominent lateral spine and measures 114 to 175 by 45 to 68 microns; the *S. haematobium* egg has a long terminal spine and measures 112 to 170 by 40 to 70 microns; the *S. japonicum*-egg has only a rudimentary lateral spine which is usually not seen. It is much smaller than the eggs of the other two species, measuring 70 to 100 by 55 to 65 microns. There would be no difficulty in making differential diagnosis on this basis, even when only portions of egg shells are available.¹⁸ In our specimens the spine was not well demonstrated, but from the size of the eggs one could readily make the diagnosis of *S. japonicum*.

A knowledge of the principal features of the life cycle of *Schistosoma* is required for an understanding of the disease produced by it and for early diagnosis and intelligent therapy. The adult *S. japonicum* typi-

cally becomes lodged in the venules of the intestines. Here the female worm deposits her eggs. (She may continue to do so for ten to twenty years or even longer if the patient survives.) Some of these eggs are extruded into the bowel and discharged with the feces. Soon after the eggs gain access to water they hatch, giving rise to fully developed, free-swimming miracidia. The miracidium seeks an intermediate host which it must find in one or two days or it perishes. If it succeeds in finding the appropriate intermediate host (a species of snail belonging to the genus *Katayama* or *Oncomelania*), it enters the soft tissues and undergoes further development and reproduction. The intermediate stage requires several weeks and is necessary for the production of fork-tailed free-swimming larvae, the cercariae, which are infective for man. (The miracidium is not infective for man). The cercariae, after leaving the snail, migrate near to the surface of the water and here may come in contact with the skin of man or mammal, their final host. If they do not find this host in one or two days, they will not survive. On coming in contact with the skin of man they lose their tails and penetrate the skin, soon to enter the cutaneous venules. The larval form is now known as the schistosomulum. It is carried by the systemic circulation through the right side of the heart and the lungs. The larvae penetrate into the pulmonary venules and pass to the left side of the heart, from which they are disseminated through the systemic arteries. It is generally believed that only those which get to the liver survive and develop to maturity. They are next found in the radicles of the portal vein where they feed and grow. Then, going against the current, they become lodged in the veins of the intestinal wall. Here maturity and mating are finally achieved. About four to six weeks after the cercariae enter the body, eggs usually begin to appear in the feces.

The pathology of schistosomiasis and the clinical manifestations can be anticipated and more fully understood with these fundamental features of the life cycle in mind. Clinically there are three generally recognized stages corresponding to (1) invasion of the body by the cercariae until maturity of the worms, (2) deposition and extrusion of eggs and (3) proliferation and repair. It is emphasized, however, that the signs and symptoms of these stages overlap one another, especially in the presence of reinfection.

The first stage, that of invasion and growth, extends from the penetration of the skin by the cercariae up to the deposition of eggs by the mature female. It lasts from four to six weeks. The symptoms may develop from five days to ten weeks after the initial invasions through the skin. As one might expect, many of the manifestations are suggestive of developing sensitivity to a foreign body, the schistosomula and the chemicals liberated from them. Urticarial wheals of the skin and mucous membranes, fever, chills and muscle pains are frequently observed. There is leukocytosis and almost always eosinophilia, which may rise to 70 per cent or more. Pulmonary signs are often prominent in the form of a dry unproductive cough and patches of increased density throughout the lung as demonstrated by roentgen rays. These are presumably pulmonary reactions to the presence of these migrating organisms in the lungs.

The second stage accompanies the deposition of the eggs. Here the eggs escape from the venules into the

tissues of the bowel wall. How this is accomplished remains unsettled, although it is believed that a multiplicity of factors may be at work. A lytic enzyme from the egg probably helps to dissolve or necrotize the wall of the vessel. The spine is so rudimentary that its presence is not likely to damage the wall of the vessel as it sometimes does in *S. mansoni* infection. However, the increased venous pressure arising from the blockage of the venule by the adult worms, together with the peristaltic movements of the gut, undoubtedly contribute to the extravasation. An intense inflammatory reaction is set up around the eggs which become lodged in the bowel wall, with the formation of small pseudo-abscesses. These often rupture, releasing the content into the bowel, causing extreme intestinal irritation associated with dysentery, distention, tenderness and fever. The stools may contain considerable amounts of blood and mucus. During this second stage anemia, leukopenia and neutropenia and hepatic and splenic enlargement often develop, but characteristically there is a drop in the number of eosinophils.

Following this trauma to the bowel the third stage gradually succeeds the second stage. It may occur from one to five years after infection and may be manifested by a cirrhotic liver, enlarged spleen, ascites, edema of the extremities, anemia, dysenteric exacerbations and cerebral symptoms such as blindness, hemiplegias and jacksonian fits. In the third stage the prolonged inflammatory reaction in the bowel gives rise to fibrosis, thickening and scarring. The eggs which are being deposited continuously find greater difficulty in getting through the bowel wall because of this scarring. They then begin to float up with the portal circulation, where they become lodged in the fine radicles of the portal vein in increasing number, or they are carried by the accessory portal circulation into the pulmonary arterioles. They give rise to intense inflammatory reaction, thrombosis and fibrosis. In the liver this gives rise to atrophic cirrhosis associated with splenomegaly, simulating Banti's syndrome. Often during this stage the stools are devoid of eggs. Anemia may be severe and eosinophilia is usually of low grade by this time.

Batson¹⁰ in his demonstration of the vertebral venous system and its role in the spread of metastases provided an equally simple, adequate explanation for the distribution of *Schistosoma* eggs outside of the closed system in which they are usually found. He also furnished a basis for explaining how nests of such eggs may be found in a focus in the brain, abdominal skin, intercostal tissues or other arteriolar focus. Faust and other investigators supported this explanation.¹⁸

Most authors have claimed that cerebral schistosomiasis occurs more frequently in the third stage than earlier in the disease. But in 4 of Carroll's 4 cases the neurologic manifestations took place in the acute stage. Carroll¹² expressed the opinion that patients having cerebral schistosomiasis in the acute stage differ somewhat in their clinical manifestations from those having cerebral schistosomiasis later.

They had the onset of paralysis . . . within the first six months of exposure. There was drowsiness usually followed by coma and incontinence. There were signs of pyramidal tract involvement with weakness, spasticity, exaggerated deep reflexes and usually Hoffman or Babinski. There was

19. Batson, O. V.: The Function of the Vertebral Veins and Their Role in the Spread of Metastases. *Ann. Surg.* 112: 138-149, 1940.

generally a high eosinophilia. As a rule the neurological signs started to improve when the temperature reached normal. . . .

Neurological involvement in the late stage was manifested by Jacksonian convulsions followed by the development of a hemiplegia but without drowsiness, coma or incontinence.

Our 2 cases apparently belong to the chronic stage of cerebral complications.

Vitug and Cruz⁹ in a report of necropsy in a case of cerebral schistosomiasis stated:

The finding of egg nests in the brain like those found in the liver and wall of the colon presented a pattern of egg distribution typical of direct deposition, according to Faust. Since there is no multiplication of the parasite after skin penetration, it is possible that, aside from the usual migration from skin to the portal circulation, schistosomes might be carried by the circulation to the brain, where they develop and deposit their eggs. From anatomical considerations the route of infestation is by way of the internal carotid artery into the left choroid and middle and anterior cerebral arteries. The location of the ova in the choroid plexus and in the subarachnoid spaces over the cerebral cortex makes possible their discharge into the cerebrospinal fluid circulation and by their own weight they may gravitate into the lumbar region. It is thus possible clinically to obtain the ova by spinal puncture and demonstrate them by microscopic examination of the fluid.

The last statement is of a speculative nature. These workers failed to find the eggs of *Schistosoma* in the spinal fluid in their 2 cases. We can find no reports in the literature stating that this has been demonstrated, nor do we believe that it will prove to be a specific diagnostic procedure for the confirmation of cerebral schistosomiasis. We are of the opinion that as soon as the eggs are deposited in the brain an intense reaction will be set up by the surrounding tissue to form a cerebral granuloma, so that the degenerated eggs are well walled off inside this low grade inflammatory mass. Consequently there would be little chance for the eggs to get into the free cerebrospinal fluid and gravitate down to the lumbar region.

Speigel,²⁰ after an extensive review of the literature and pathologic study of surgically removed specimens, concluded that "there is evidence that the adult parasite may reach the brain either by ascending against the venous stream to the cerebral tissue or by traveling with the blood stream to the brain as arterial emboli." Greenfield and Pritchard¹³ stated that "the earliest symptom of cerebral involvement by the ova is usually focal epileptic seizures and the left hemisphere is most frequently involved."

Meleney²¹ gave an outline of the medical treatment of schistosomiasis. He mentioned the use of stibophen, potassium antimony tartrate and emetine hydrochloride. If the disease is attacked medically in the first or second stage, before showers of eggs have reached the liver, the prognosis is generally favorable. If, however, the liver has been invaded by a large number of eggs, the inflammatory reaction, thrombosis and fibrosis may lead to irreparable damage and atrophic cirrhosis, terminating in death in three to five years or more. Meleney and some investigators²¹ stated the belief that stibophen is the best antimony preparation for the treatment of schistosomiasis. It was considered as standard treatment in 1943 primarily because of the

experience of Khalil²² in Egypt. But Lee²³ found it unsatisfactory for oriental schistosomiasis and the failure of the drug, even when employed in almost doubly recommended dosage, was amply documented by American and Australian experience on Leyte. Faust (cited by Speigel²⁰) stated that the most satisfactory therapeutic results are obtained by administering antimony potassium tartrate (0.5 per cent solution) over a period of four weeks with a total of 320 cc. of the solution, or 0.576 Gm. of metallic antimony in the drug. He expressed preference for the use of antimony potassium tartrate rather than stibophen by stating that "105 cc. of Fuadin containing 0.941 Gm. of metallic antimony is not invariably curative." The present recommendation approved by the United States Army is to employ a 0.5 per cent solution of potassium antimony tartrate intravenously, beginning with 6 cc. and working up to 24 cc. on alternate days, until approximately 0.6 Gm. of metallic antimony has been administered. In spite of this statement, stibophen is still being widely used in the United States Army. Some investigators still express the opinion that stibophen is the medicine of choice for the treatment of schistosomiasis, especially in chronic cases.

For cerebral schistosomiasis, and from the neurosurgeon's point of view, we strongly recommend craniotomy as an adjuvant to the medical treatment, when there is evidence of a localized expanding lesion. We believe that craniotomy and biopsy are the only definite means of confirming the diagnosis in cases such as the 4 here reported in which there is not a definite history of an acute stage or in those cases which have passed the acute stage with treatment some time previously. For lesions situated on the surface of the brain and well localized in one area, complete removal can sometimes be achieved. Craniotomy also has the effect of relieving the intracranial tension which might be an impending danger in certain cases of schistosomiasis of the brain. Should circumstances prevent the carrying out of craniotomy with impunity, a subtemporal decompression should be done immediately to relieve the increased intracranial pressure; this we believe at times is a life-saving procedure and might well prevent the loss of eyesight in some cases in which a great increase in intracranial pressure occurs.

Without the aid of craniotomy, the diagnosis of cerebral schistosomiasis cannot be made with certainty; at best it may be strongly suspected in a given case, but a neoplasm or histoplasmosis cannot be ruled out. Clinically the diagnosis is established with the aid of (1) history of exposure, (2) clinical manifestations, (3) demonstration of the eggs in the stool specimen and (4) eosinophilia. Tillman¹⁴ mentioned in his paper the differential diagnosis of cerebral schistosomiasis from other cerebral diseases. As a whole, all the clinical diagnostic points are indirect and presumptive, except when eggs can be found. Faust¹⁸ expressed the opinion that, if good laboratory assistance is available and is supplemented by proctoscopic studies, all or essentially all of these cerebral cases should have adequate confirmatory diagnosis.

Speigel²⁰ in January 1947 reported a case of cerebral schistosomiasis in which treatment was by surgical

removal of an intracerebral mass of *Schistosoma* eggs and added 2 more cases from the literature to the list of 8 cases given by Carroll;¹² i. e., one of Shimidzu²⁴ and one of Edgar.⁷ Faust²⁵ stated that a year after the first exposure following the landing of the American military forces on Leyte, on Oct. 20, 1944, more than 1,000 cases of schistosomiasis japonica had been studied in the army general hospitals; from these Thomas and Gage²⁶ reported 2 with neurologic lesions which had been observed before return to the United States. Faust also mentioned 3 other cases which he saw in the 118th General Hospital on Leyte and presented a clinical case referred to him by Speigel and an autopsy case by McNamara. Watson and others²⁷ reported a case of schistosomiasis of the brain due to *S. japonicum*: The patient was infected on Leyte

were confirmed by autopsy.²⁸ Three cases of surgical removal of a mass of *S. japonicum* eggs were cited by Speigel; namely, 1 by Shimidzu²⁴ and 2 by Greenfield.¹³ Speigel's case was the fourth one. Watson's case was the fifth one. The present report adds 4 cases to this list.

SUMMARY AND CONCLUSIONS

A brief review is given of the literature on cerebral schistosomiasis, and the principal features of the life cycle of *Schistosoma* are outlined. The fate of the worm, the deposition of the eggs in various parts of the body and the genesis of schistosomiasis of the brain are discussed.

Four cases of cerebral granuloma caused by *Schistosoma japonicum* eggs, seen in the brain of living subjects on the operating table, are presented. In our second case, a correct diagnosis was arrived at before craniotomy. All four cases were confirmed by microscopic section made from the biopsy specimens.

The medical treatment for schistosomiasis is discussed. Craniotomy is recommended as an adjuvant to the medical treatment for cerebral schistosomiasis.

Our 2 cases, together with the 2 studied by Dr. Saunders, have a fivefold significance: (a) they are to our knowledge the eleventh, twelfth, thirteenth and fourteenth pathologically proved cases of cerebral schistosomiasis japonica, and the sixth, seventh, eighth and ninth cases treated by surgical removal reported in the world literature; (b) they illustrate the possibility of cases of cerebral schistosomiasis presenting themselves as diagnostic problems in this country thousands of miles from where *S. japonicum* is endemic; (c) they present some of the criteria by which the diagnosis may be made; (d) our second case illustrates that the diagnosis can be made or strongly indicated preoperatively if there is sufficient awareness of the disease, and (e) neither of our patients gave a history of having had symptoms and signs indicating the acute phase of schistosomiasis before they had the neurologic manifestations. A history of early systemic schistosomiasis is not necessary in the diagnosis of cerebral schistosomiasis.

and had convulsive seizures one hundred and fifty-six days after the exposure. Craniotomy was done twice, with much improvement of the patient's condition.

To summarize all the reported cases of cerebral schistosomiasis, with regard to treatment, table 2 is presented.

As shown in the table, up to the present time there are 38 reported cases of schistosomiasis of the brain; in 5 of these treatment was by craniotomy and surgical removal of the mass of *S. japonicum* eggs. Of these 38 cases 5 were surgically proved. The other 33 cases were diagnosed on a clinical basis, and a small number

Arteriosclerosis and the Ductus Arteriosus.—The ductus arteriosus is a true muscular organ which on proper stimulation is capable of contracting strongly enough to obliterate its lumen. The stimulation is apparently the increase of the oxygen saturation of the arterial blood brought about by the onset of respiration in the newborn infant. After the contraction has been maintained for several days, actual histologic changes take place. Muscle tissue is replaced by tissue of a lower order of specialization. In some cases, the replacement is slow, and no necrosis occurs; however, in others rapid degeneration with necrosis and calcification takes place. The cause of this tissue replacement and degeneration appears to be relative anoxemia of the wall of the ductus brought about by contraction of the muscle. This contraction narrows the lumen, compresses the vasa vasorum and thus decreases the blood supply of the vessel wall. These tissue changes occurring in the ductus arteriosus as the result of anoxemia seem to be similar to those observed by Hueper in arteriosclerosis. The work recorded in this paper, therefore, leads to the opinion that anoxemia plays a large part in arteriosclerotic processes and may possibly be the fundamental mechanism through which the various causal agents bring about arteriosclerotic changes.—Blumenthal, Lester S., Pathologic Significance of the Ductus Arteriosus, *Archives of Pathology*, October 1947.

PERIODIC DISEASE

A Probable Syndrome Including Periodic Fever, Benign Paroxysmal Peritonitis, Cyclic Neutropenia and Intermittent Arthralgia

HOBART A. REIMANN, M.D.
Philadelphia

Because of their rarity, or because they are overlooked, disregarded or mistaken for other conditions, little attention has been paid to certain peculiar, benign syndromes which last several days and recur for years at remarkably regular, short intervals. In naming them the adjectives periodic, cyclic, rhythmic, episodic, relapsing, paroxysmal, recurrent and intermittent are used interchangeably before the noun indicating the outstanding characteristic, as noted in the title and in the references. In this paper, studies of 6 patients with periodic diseases, three featured chiefly by fever and abdominal pain, one by neutropenia, one by arthralgia and one by myasthenia, are reported and compared with those of similar and different periodic diseases which have been noted by others. Each causes periods of temporary disability, which recur for years with predictable accuracy and uniformity. Since all 6 patients are under observation, the duration and outcome of their ailments cannot be stated.

PERIODIC FEVER

CASE 1.—The detailed report of study of this patient, Mrs. N. W., aged 49, appears elsewhere¹ and, in brief, is as follows: There is no record of tuberculosis, syphilis, rheumatic fever, mental disorder, epilepsy or migraine in the family. The patient had epileptiform attacks which ceased when menstruation began at 14 years of age. She had two difficult pregnancies; the last in 1921 was complicated by pyelitis. Her present trouble began in 1936 with spells of irritability, chilliness and sweating which occasionally obliged her to spend a day or two in bed and were mistaken for the signs of early menopause. She soon noticed that the episodes recurred at regular intervals of seven-teen to twenty-one days and were accompanied by fever and other symptoms. Death of her husband in 1941 caused mental depression for several months, and the febrile episodes became more severe. She first entered the hospital in 1941. Because of the pyelitis in 1921 and the presence of abdominal and lumbar pain, pyelitis of banal or tuberculous origin was suspected but ruled out for lack of evidence. The patient came under my observation in 1943 and was studied during numerous long periods in the hospital up to the present.

The bouts have gone on without much change in their nature for eleven years. They last five to seven days and recur with such regularity every seventeen to twenty-two, usually eighteen, days that the onset of each subsequent one can be predicted with as much accuracy as the menstrual period (chart 1). The menstrual periods occur in regular twenty-seven to twenty-nine day cycles and have no obvious relation with, or influence on, the febrile attacks whether they coincide or not. The febrile episodes are often preceded by an increase of the pulse rate and begin with a feeling of warmth, restlessness, irritability and aching and a rise in temperature. In a day or two the irregular temperature reaches 39 C. (102 F.) and occasionally 39.5 C. (103 F.), with weakness and malaise as constant features. A chill or chilliness, flushing, nausea, vomiting, headache and pains in the abdomen, flanks, arms, hands, legs and feet with tingling occur in varying combinations and degrees of severity during different episodes. In the intervals between attacks the patient feels well. Her weight is normal and constant.

In repeated examinations during the last six years no significant abnormalities were detected in the free periods. During

the bouts, there is flushing, slight puffiness of the face and occasional sweating. Rectal temperature readings matched oral ones. Roentgenographic study showed no abnormalities in the chest or abdomen. Several electrocardiograms and encephalograms were normal. Pelvic, neurologic and psychiatric examinations revealed no disturbances. Laboratory studies were not helpful. The erythrocytes, hemoglobin, urine, blood pressure and basal metabolism were normal. Renal and hepatic function tests, tests for agglutination and cutaneous tests for numerous bacteria, the fragility test, the Congo red test, the Wassermann test, the heterophil antibody and cold agglutinin tests and blood cultures all gave negative results. Estrogens, gonadotropins and pregnandiol were excreted in normal amounts. The only abnormalities are occasional panleukopenia (2,000 to 3,000 cells) at irregular intervals not related to the fever, constant monocytosis (between 7 and 21 per cent), a persistent increased sedimentation rate of about thirty minutes and an increased amount of globulin in the blood. On several examinations the sternal marrow contained an increased number of eosinophils, basophil cells and plasmacytes.

Several procedures failed to modify the rhythm of the febrile bouts. The menstrual cycles were disturbed at different times by the administration separately of diethylstilbestrol, estradiol benzoate, progesterone and testosterone propionate without significantly altering the febrile attacks. Thyroid substance, quinine sulfate, sodium diphenylhydantoin and roentgen therapy directed at the spleen also caused no changes. On one occasion, antityphoid vaccine injected intravenously caused its usual febrile reaction three days before an expected episode, which occurred punctually but consisted of only two days of slight

Chart 1 (case 1).—Episodes of fever and tachycardia lasting five to seven days and recurring every nineteen to twenty-one days, in no relation to the menstrual periods. Aminopyrine depressed the fever; "amytal" narcosis had no effect.

fever. The procedure was repeated but without a similar effect. Antipyretic drugs depressed the temperature, contrary to their ineffectiveness in the hyperthermia related to menstruation.² Sedatives had no effect.

Up to the present (December 1947) the episodes recur unchanged. No additional physical or other changes have developed. No cause for the condition has been discovered and no evidence of Hodgkin's disease, neoplastic disease, infection, neurologic, allergic or psychic disturbance or of hereditary influence is present.

CASE 2.—S. L., a Jew, aged 27, ten years previously noted periods of headache and vomiting every month or two. They were supposedly of nervous origin caused by discomfort or poor food while living away from home. The episodes began with pain in either side of the chest, shoulders or abdomen, severe headache, aching of the extremities, nausea, usually vomiting, and temperature of 39.5 C. (103 F.). They lasted about two days and were separated by intervals of good health. The intervals gradually shortened to thirty day cycles, finally to seven days. For a period of six months, while a limited diet was being taken, the attacks ceased, but they were resumed in 1939 after immigration to the United States. He was extensively studied at several hospitals where some teeth, his tonsils and appendix were needlessly removed. All studies, including exploratory laparotomy, gave no clues as to the cause.

Despite his record he was inducted into military service in 1941 and carried out his duties except for the weekly inter-

From Jefferson Medical College and Hospital. Presented before the Medical Association of Puerto Rico, San Juan, Dec. 12, 1946, and the California State Medical Association, Los Angeles, May 2, 1947.

ruption by his ailment. For this he was again extensively studied in several army hospitals, but was sent overseas where the attacks were worse. He was returned to this country in 1944 and spent six months in another army hospital, where all roentgenologic and laboratory studies, cystoscopy, proctoscopy, skin tests and others failed to yield helpful information. The only findings were repeated attacks of fever, as shown in chart 2, with leukocytosis. Courses of sulfonamide compound, penicillin and emetine therapy did not influence the fever. He was discharged as having febricula, cause undetermined. He then entered another hospital in 1946 for herniorrhaphy, and was finally referred to me by Dr. Edward Weiss in January 1947.

Because the patient is employed and cannot afford to spend time in the hospital for studies, he recorded his own temperature, as shown in the right half of chart 2, and his symptoms. The episodes have lessened somewhat in severity, and he is able to remain at work if acetylsalicylic acid is taken during them. They recur every five to nine days, usually every seven. On one occasion before an expected episode he entered the hospital for study but was displeased with the ward accommodation and left the next day. For unknown reasons or perhaps because of this disturbing experience, for the first time in many months the slight early symptoms failed to deepen and the oral temperature rose slightly but remained normal. The rectal temperature rose to 37.9 C. (100.2 F.), as shown in chart 2. The next bout recurred on time in its usual form and the temperature rose higher since he refrained from taking acetylsalicylic acid. The pulse rate, usually 74, was 120 per minute, and he was pale and dry. Hirsutism is prominent. There was abdominal tenderness on pressure, but no other abnormal signs. The leukocytes numbered 11,500, with 70 per cent polymorphonuclear

Chart 2 (case 2).—Episodes of fever lasting a day or two at five to eight day intervals recorded at an army hospital in 1943, and during current observation. On one occasion in 1947 the rectal temperature alone reached fever levels.

cells, 20 per cent lymphocytes and 10 per cent monocytes. The erythrocytes and hemoglobin were normal. Between episodes his leukocytes number 7,000, he appears to be healthy and well adjusted, and his weight is normal. Six hours of fever caused by the intravenous injection of antityphoid vaccine during one free interval suppressed the next expected episode, but the following one occurred punctually and unchanged.

CASE 3.—A physician, aged 37, first noted attacks of "peritoneal irritation" three years previously, in May 1944. They have recurred at intervals of two to six weeks, usually four weeks, with good health between them. An episode begins with pain in the abdomen, tenderness to pressure and colic. The temperature rises to 38.9 C. (102 F.). Nausea and occasionally diarrhea occur, but no vomiting. The leukocytes rise to 12,000 to 19,000 in number with no disturbance in the proportion of component cells. After twenty-four to thirty-six hours the temperature becomes normal but the symptoms persist forty-eight to sixty hours. All studies to determine the cause of the condition have been unhelpful.

Other patients with conditions remarkably similar to the one just mentioned have been described. Janeway and Mosenthal³ in 1908 observed a Jewish girl of 16 who had had recurrent attacks of fever and abdominal pain since early infancy. The intervals at first were monthly but later shortened to seven days. During this time there was only one ten week period free from attacks. The attacks varied in intensity; occasionally one would be symptomless, but the tem-

perature rose slightly, on schedule. In the severe ones there were prostration; anorexia; colic; pain in the shoulders, hips and feet, as described in cases 1 and 2; a temperature of 40 C. (104 F.); tachycardia; leukocytosis (28,000 cells), and an increase in the excretion of uric acid and creatinine. There were salivation, nausea, belching and occasionally vomiting. The discomfort lasted eight to sixteen hours. Abdominal rigidity suggested peritonitis but appendectomy had no effect. Immediately after an episode the leukocyte count returned to normal but with polymorphonuclear leukopenia (30 to 36 per cent). No eosinophilia was recorded.

Cooke⁴ made further studies of the patient twenty-four years later which he reported in 1933. An allergic basis was suspected as the cause, although all tests for protein sensitivity were negative. After milk was withdrawn from the diet, attacks were said to have stopped. Joslin, who discussed Janeway's paper in 1908, cited an almost identical case in a nursemaid, but no details are available. Alt and Barker's⁵ patient, a youth of 18, had attacks of abdominal pain, pain in the right arm, shoulder and chest, vomiting, occasional splenomegaly, fever and polymorphonuclear leukocytosis (20,000), beginning at the age of 4 and recurring at first four to six times a year, then gradually oftener until the interval was a week, and when the patient was last heard from, three or four days. Removal of an enlarged spleen had no effect on the recurrent attacks, which were observed for thirteen years. The patient was otherwise well. His brother was said to have identical attacks.

Scott and Kirshner⁶ described a patient whose episodes begin between 5 p. m. and 6 a. m. with itching and urticaria, followed by a chill, malaise, temperature of 40.5 C. (105 F.), leukocytosis and occasionally arthralgia. They recur at intervals of forty-eight hours to seven days, usually two to three days, and last eighteen hours. He is well in the free periods. Tests for sensitivity to numerous proteins gave negative results. Various forms of treatment including foreign protein shock and transfusions had no effect. According to a letter from his present physician, Dr. T. H. Gillison in England, the man, now 41 years old, is still having his attacks after fourteen years. Some form of allergic edema is suspected to affect the heat-regulating center.

Wolf and Wolff⁷ reported the case of a man of 43, previously studied by Allen,⁸ whose episodes were characterized by fever, leukocytosis and pain in the abdomen and extremities. They lasted about twelve hours, recurred weekly and were observed for twelve years. They apparently replaced migrainous episodes which had recurred in six preceding years. The patient was emotionally unstable; the fever at times seemed to be related to psychic influences, and the episodes were influenced by sodium diphenylhydantoinate. The patient's father had similar episodes for fifteen years between the ages of 25 and 40. They stopped spontaneously.

Under the title benign paroxysmal peritonitis, Siegal^{9a} reported 10 similar cases, 8 of which were

in males. The abdominal pain attracted more attention than the fever; hence the name. The periodicity was recorded in weeks or months over many years. Allergy was suspected as an underlying cause in most instances.

Fever occurred with leukocytosis in most of the patients thus far described or cited; in Rutledge's and Reznikoff's patients, to be mentioned later, neutropenia accompanied the febrile episodes.

Better known are the instances of fever, or temperature at fever levels, which occur periodically in many healthy women during the latter half of the menstrual cycle to which they are related.⁹

CYCLIC NEUTROPENIA

CASE 4.—L. F., a Jew, aged 20, is under study by Drs. Tocantins and Woldow, whose detailed report will appear elsewhere. He was discharged from the army because of repeated episodes of leukopenia and disability, first noticed in June 1945. He was studied at this hospital on many occasions. During one study, from December 1945 to April 1946, there were five recurrences at intervals of twenty to twenty-two days, each lasting from five to seven days (chart 3). Between times he felt well although the leukocyte count at all occasions numbered from 3,000 to 4,500 per cubic millimeter of blood, owing to the low number of polymorphonuclear cells. Except for variable but increased numbers of monocytes to compensate for the neutropenia, all other cellular elements of the blood were normal.

The episodes begin with a progressive fall for two or three days, sometimes to zero, in the number of polymorphonuclear cells, accompanied by increasing malaise, headache, sore throat and aching of the body. Tenderness and swelling of the anterior cervical lymph nodes and small ulcers on the tongue and oral mucosa occur. There is seldom any fever or other significant abnormality. The symptoms and signs then gradually abate, the neutrophilic cells increase in number and the patient feels well until the recurrence, the onset of which can be accurately predicted.

This case closely resembles 3 other reported ones. One patient, who during infancy was studied by Leale,¹⁰ was described in 1930 by Rutledge¹¹ when the man was 19 years old and again by Thompson¹² in 1934. He had psychic disturbances and episodes of disease with oral ulcers, granulopenic leukopenia and fever, which lasted from three to ten days and recurred with predictable accuracy at twenty-one day intervals. Between recurrences he was well but unstable emotionally. Communication with this patient eleven years later in 1945 when he was 34 years old, just before death from pneumonia, revealed that the neutropenic cycle persisted at twenty-one day intervals but the constitutional symptoms had disappeared.

Doan's¹³ patient, a woman of 18, had recurrent neutropenia lasting several days accompanied by dermal and oral ulcers at regular eighteen to twenty-one day intervals independent of menstruation, and without fever. During the recurrences, there was relative or absolute neutropenia with a total leukocyte count of 2,000 to 3,000. The monocytes often rose to 50 per cent of the total number. In addition, the patient had congenital hemolytic icterus. After splenectomy, the leukocytes did not fall below 5,000 per cubic millimeter,

but the number of granulocytes continued to fluctuate in the usual rhythm to a lesser extent. It is now sixteen years since the condition was first noted.¹⁴ The patient's mother had hemolytic icterus but not leukopenia.

Reznikoff¹⁵ reported the case of an 18 year old youth who had periodic attacks of fever, "canker sores" and abdominal pain since infancy. The episodes occur every twenty-one days, each lasting ten days, of which four are usually spent in bed because of the severity of symptoms. Leukopenia concurrent with the bouts was discovered at the age of 13. The leukocytes diminish in number to 2,000 or 3,000 per cubic millimeter; the neutrophils vary from 2 to 15 per cent of the cells present. During the depression, the total marrow cell count falls to 1,800. The excretion of 17-ketosteroids measured over a three month period was diminished after the onset of each episode. After splenectomy, the leukocyte count, as in Doan's patient, did not fall so low as before, but the symptoms except for lesser abdominal pain were not changed.

All 4 patients just described had recurrent neutropenia and stomatitis in cycles of twenty-one days. The febrile cycles in case 1 are similar in length but without stomatitis or regularly concomitant neutropenia. Both sexes are affected. In all 5 the cycles recurred every

Chart 3 (case 4).—Recurrent neutropenia, oral ulcers, headache and malaise lasting eight to ten days and recurring every twenty-three to twenty-six days. The diminution of neutrophilic cells precedes the clinical symptoms represented by shaded bars to indicate their gradual increase and decrease in intensity.

seventeen to twenty-two days for years; in each there were leukopenia and numerical increase of the monocytes, and each enjoyed good health in the interims. The similarity of behavior suggests that the disease represents a syndrome with a common but unknown cause to which the following periodic conditions may be related.

CYCLIC THROMBOPENIC PURPURA

Demmer¹⁶ reported the case of a 61 year old man who had been impotent for eighteen years and whose family contained members with mental disorder. The patient had regular, predictable periods of purpura every twenty-eight days for six years. Studies during the last few periods before death from chronic nephritis revealed cyclic severe thrombopenia preceding and accompanying purpura. The leukocytes usually were normal in number except for irregular periods of relative neutropenia and compensatory lymphocytosis. Demmer suspected some endocrinologic disturbance as the cause of the condition because of similarity of the temporal rhythm of the episodes to menstrual periods and of the patient's impotence.

INTERMITTENT ARTHRALGIA

CASE 5.—Mrs. C. B., aged 31, first noticed fleeting pain and stiffness in the right elbow in August 1944. The discomfort lasted a day or two and recurred regularly every thirteen or fourteen days. Three months later, the left knee began to hurt and swell at about the same time, but more severely than the elbow. Walking was painful. In time the disturbance of the knees alone retained its regularity, the stiffness of the elbow either preceding, accompanying or following it and sometimes not occurring at all. The pain and swelling lasts seven or eight days, leaving a free interval of similar duration. Since March 1946 the right knee is synchronously involved though less severely. The rhythm is illustrated in chart 4. Since the menstrual periods recurred in twenty-seven day cycles, alternate attacks of the arthralgia every thirteen or fourteen days coincided for a time with the former, but a subsequent shortening of the menstrual cycle led to unrelated dissociation. In April 1946 two attacks of paroxysmal tachycardia occurred, and in June symptoms and roentgenographic evidence of a duodenal ulcer responded to dietary treatment. Painful spasm in the calf muscles occur without relation to the arthralgia. Quinine sulfate gives relief. Aside from a persistent emotional disturbance and occasional mental depressions which develop from marital incompatibility, there are no other obviously relevant factors in the patient's recent or past history. Her father died from hypertensive disease; her mother and brother are well.

The patient was observed in the hospital on numerous occasions. Except for the swollen left knee during the episodes and the duodenal ulcer, repeated examinations reveal no abnor-

Chart 4 (case 5).—Intermittent arthralgia, lasting five to eight days in the left knee, recurring every thirteen to fifteen days; lesser symptoms in the right knee lagging behind those of the left, and stiffness of right elbow at less regular intervals. Because of the overlapping, there are but few symptomless days. Episodes of arthralgia are in no relation to the menstrual periods.

malities. The pulse rate averages 85, but varies from 60 to 90 beats per minute; fever has not been detected. Electrocardiographic tracings and roentgenograms are normal. Laboratory studies, including agglutination and skin tests for brucellosis, all give negative results. On one occasion 10 cc. of cell-free sterile cloudy fluid was withdrawn from the knee joint.

Experimental therapy with diethylstilbestrol, estradiol, calcium gluconate and vitamin D failed to disturb the regularity or severity of the attacks, although diethylstilbestrol suppressed one menstrual period. Tight binding and roentgen therapy to the left knee failed to relieve the pain or swelling.

The literature on the subject of intermittent arthralgia or hydrarthrosis was reviewed by Comroe.¹⁷ About 120 cases are on record. The cause is unknown, but in certain patients brucellosis, allergy, malaria, lymphogranuloma venereum, psychic factors and endocrine disturbances seemed to be the underlying causes. In some patients arthralgia occurred with the menstrual period and in others it was temporarily relieved during pregnancy. In some instances several members of a family were afflicted. The cycle of attacks in various patients ranged from seven to twenty-one days.

RECURRENT MYASTHENIA

CASE 6.—A. P., a man aged 64, was admitted Oct. 1, 1946, complaining of pain in his left shoulder and chest and generalized weakness for nearly two years.

17. Comroe, B. I.: *Arthritis and Allied Conditions*, Philadelphia, Lea & Febiger, 1941, pp. 589-593.

About two years previously he first noticed occasional difficulty in keeping his right eye open, except by a brace fixed to his glasses. He continued to work but noticed the gradual development of periods of weakness. After four or five months, his arm at intervals would tire so much after using a hammer that he had to change hands or rest until strength returned. Presently the weakness included his legs. Later, severe dysphagia was added to the symptoms. Speech was inarticulate, but would improve after thirty minutes of rest, to relapse after further use. Early in an episode, weakness of the legs made it difficult to stand. After seven to ten days strength would return and normal activity could be resumed except that his former vigor was never regained. In the course of time he noted that the episodes lasted from seven to ten days and were separated by similar free intervals describing a periodicity of fourteen to twenty days.

On admission to the hospital on October 1, the patient lay listlessly in bed, unable to sit up. Speech was interrupted by needed periods of rest before resumption. Both lids drooped. Food was swallowed with difficulty and often entered his nose. Shortly after admission, aspiration pneumonia developed and lasted four days. Except for evidence of loss of weight, muscular weakness, hyperactive biceps, triceps, radial and patellar reflexes and difficulty in speech, the examination was negative in result. The Jolly reaction was positive. A diagnosis of myasthenia gravis was suggested.

Injection of 3 mg. of neostigmine methylsulfate gave striking improvement in thirty minutes which lasted about five hours. By the tenth day, October 10, remission occurred and the patient was able to walk about, but felt weak and tired easily. The Jolly reaction was negative. Partial ptosis of the right lid persisted. The amount of potassium in the blood was normal during and between the episodes.

On October 24, after two weeks of comparative well-being, he noted loss of control of his tongue, then of swallowing, followed by weakness of his arms, then his legs. Another attack of aspiration pneumonia occurred on October 25, and lasted six days. The Jolly reaction again was positive. Shortly after the injection of 3 mg. of neostigmine he ate his meal without difficulty. General improvement began about November 1, and soon he was nearly normal for about a week, when difficulty in swallowing reappeared, on November 8, but lasted only a day. This recurred on November 13, but disappeared after a day with no further recurrence under therapy with neostigmine. The episodes may have been interrupted by the two attacks of pneumonia or more likely by therapy with neostigmine.

During the course of study the question was raised of familial periodic paralysis which like myasthenia gravis appears intermittently but with regularity. The condition is usually, but not always, hereditary and the triad of paroxysmal, flaccid paralysis, loss of reflexes and of electrical excitability and disturbance of potassium metabolism is said to be characteristic.¹⁸ Episodes recur often with regularity at intervals of a few days to a few months.¹⁹ The suggestion is made that it is caused by an inborn error of metabolism or a disequilibrium of the vegetative nervous system with evidence of periodic intoxication, which does not clarify the problem much.

COMMENT

No satisfactory explanation accounts for the regular recurrences of fever, neutropenia, arthralgia and myasthenia in the cases described, or why they take place so punctually and uniformly for so long without interfering with the general health of the patients. Recurrences of fever or other signs, symptoms and laboratory evidence are well known in Hodgkin's disease, non-suppurative relapsing panniculitis, undulant fever, relapsing fever, malaria, migraine, epilepsy and in cer-

tain psychoses, but they are not so uniform and predictable; for the most part the diseases are eventually recognized by specific changes; they progress or regress, and in some instances the cause is known. However, a regular periodicity of fever was observed in a high proportion of Ask-Upmark's^{19a} series of 352 patients with tumors of the bones, leukemias and anemias.

The episodic diseases in question do not coincide with, or appear to be related to, any known natural intrinsic rhythmic fluctuation such as the menstruation, the estrous cycle of animals, hibernation or the seasonal variation in the number of blood platelets.²⁰ On the other hand, each of the conditions mentioned; namely, fever,⁸ neutropenia with stomatitis,²¹ thrombopenic purpura,²² swelling of the breasts and hydrarthrosis¹⁷ in many other cases has been observed to be synchronous with the menstrual periods and appears to be caused either by the rhythmic endocrinologic changes incident thereto or is precipitated by them. But despite the apparent dissociation of menstruation with the periodic conditions in the cases herein reported or referred to, various authors still suspect the operation of some neuroendocrinologic factor to account for them. Thompson,¹² for example, demonstrated neutropenia in a man synchronous with a fluctuation in the excretion of estrogenic substance similar to the hormonal cycle in women; and in Reznikoff's¹³ male patient, the excretion of 17-ketosteroids was diminished after the onset of the episodes, but similar changes were not present in case 4 of this report. Nor did Stephens and Lawrence^{21c} find a correlation in the excretion of female sex hormone with neutropenia in a female patient who had neutropenia during the menstrual periods. Demmer¹⁰ suspected an endocrinologic basis because of the twenty-eight day cycles of thrombopenic purpura in his impotent male patient, and the same was suggested to account for the periodic swelling of the breast in another impotent male patient.²³ Other observers believed the condition which they described to be connected in some way with hypersensitivity to proteins,²⁴ but the cases they presented and cases 1, 2 and 3 of this report have none of the manifestations of allergy as described in a case of allergic peritonitis.²⁵ Epileptic,⁷ migrainous⁷ or psychopathic²⁶ tendencies have also been held responsible. Since periodic fever as studied by Ask-Upmark^{19a} was encountered mainly in disorders affecting the bone marrow and spleen, the reticuloendothelial system was considered as an important factor in the regulation or disturbance of body temperature. There is indeed evidence of the involvement of the reticuloendothelial system in the cases of periodic fever, neutropenia and thrombopenia as here described, but not in intermittent arthralgia nor in recurrent myas-

themia. It is possible that these conditions are the manifestations of cyclic changes, not necessarily the cause of them. Even if they were, the enigma of regular periodicity would still remain. In some instances,²⁷ and in familial periodic paralysis,¹⁸ a genetic factor is obvious. Emotional disturbance may play a role^{20d, e} in some recurrent conditions but not always in regular cycles over long periods.

Possible Hormonal or Other Cyclic Changes in Men.

—Of the 28 cases of periodic conditions herein discussed or mentioned, 21 were in men. Since, as stated earlier, each of the various clinical conditions at times occurs synchronously with the menstrual cycle or is activated by it in women, there may be an analogous, as yet undetected, cycle in men signalled in similar instances only by the synchronous periodic appearance of the same variety of signs, symptoms or other changes. Support of this possibility rests on a form of climacterium observed in certain men and the suspicion of sexual endocrinologic relationship in men mentioned in the preceding paragraph.

Facts opposed to this proposal are the independence of the periodic conditions from the menstrual cycle in cases 1 and 5 and in Doan's¹³ patient, the absence of evidence of synchronous hormonal excretion in case 4 and the onset of the episodes in infancy in the patients of Janeway,³ Rutledge,¹¹ Alt and Barker⁵ and Reznikoff.¹⁵ The circumstance in the case of habitual hyperthermia reported elsewhere,^{2b, d} in which "fever" was first noted at the age of 5 and later assumed synchrony with the menstrual cycle, suggests that sexual endocrinologic influence does not necessarily cause the various symptoms in either sex but may provoke a latent condition to a degree sufficient for clinical recognition in rhythm with its own cycle.

Regardless of a possible dependence on sex hormonal influence, there are curious cyclic changes in both men and women in the cases described. These may represent the exaggerated forms of similar inherent but symptomless rhythms in many persons which would be detectable only if measurable and countable elements like the erythrocytes, leukocytes, platelets, basal metabolic rate, temperature, pulse and others were accurately registered over long periods. The episodes may rise to clinical significance at any age from infancy²⁸ to the sixth decade (Demmer,¹⁰ case 6) and may stop spontaneously⁷ or during treatment (Cooke,⁴ Ask-Upmark,^{19a} case 6). One may suggest that in the cases presented certain changes occur in the body or certain factors build up or accumulate to a point at which symptoms and signs are caused to reach clinical significance, then dissipate and repeat the cycle regularly and indefinitely, but thus far, in most instances, none of the experimental procedures or theories has indicated the underlying cause or significantly influenced their behavior. They may be unrelated medical curiosities, or more probably, some or all of them may have a common underlying basis to weld them as a syndrome of periodic disease with different manifestations. It is important to know that such benign periodic conditions exist in order to protect the victims from unnecessary diagnostic expense and discomfort and from the hazards of unnecessary therapeutic and surgical procedures.

A curious fact emerged after the accompanying table was prepared grouping my own cases with those of others; namely, that in each case the periodicity in

days is about 7 or multiples of 7. The same is reported in intermittent arthralgia,¹⁷ in Siegal's^{2a} tables and is shown in many of Ask-Upmark's^{19a} charts. Some, so inclined, may attach mystic significance to this, particularly in respect to the age-old importance associated with the numeral 7 and of the numerous allusions to it.²⁰ It was suggested that a latent or overt cyclic rhythm of this duration in mankind led to the establishment of the seven day week not on an astrologic or religious basis, but as the projection of a physiologic periodicity.³⁰ Whatever interpretation or explanation one wishes to make, the periodicity in the cases described seems to be too consistent to be fortuitous. It may be fantastic to cast about for some possible bearing of extrinsic cycles on the conditions described except to mention them. The rhythm of the days, the weather, the seasons and the sun spots are a few,³¹ but the lunar cycle lasts about twenty-nine days and

LYMPHOMAS AND LEUKEMIAS

The Value of Early Diagnosis and Treatment

LLOYD F. CRAVER, M.D.
New York

This article is the seventh of a series to be published by the American Medical Association in cooperation with the American Cancer Society. The series is designed to aid in the early diagnosis of cancer and thereby to gain more effective results in treatment. When complete, the series will be published in book form by the W. B. Saunders Company under the sponsorship of the American Medical Association and the American Cancer Society.

There is at present a large hiatus in diagnosis of cancer. On the one hand, persons who presume that they are well flock to the so-called cancer prevention clinics where, despite the expenditure of considerable time, effort and money, relatively few cancers are found. On the other hand, the clientele of the centers for treatment of cancer is mostly made up of patients who have well established malignant neoplasms. Analysis of the reasons for delay in treatment of the latter group discloses that a large share of the responsibility for delay continues to rest on the first physicians consulted by the patients having cancer and that it is questionable whether since 1938¹ the physician's relative share of the responsibility has been reduced.²

This diagnostic hiatus which exists for cancer in general seems to be particularly noticeable in the lymphoma-leukemia field. Few lymphomas or leukemias are found in a cancer prevention clinic that limits its examinations to those who are unaware of the existence of a condition suspected of being a neoplasm. Yet those who apply for treatment of a lymphoma or leukemia have, for the most part, a well established disease process.

The reasons for the diagnostic hiatus in the lymphoma-leukemia field appear to be mainly the following two: (1) failure on the part of the practitioner to recognize the significance of early signs and symptoms and (2) failure on the part of the practitioner to be aware of or to accept the value of early treatment. Unfortunately the assumption of lack of value of early treatment has been unjustifiably bolstered by the dicta of some who should be in a position to give better advice. In this argument it must be admitted at once that no case of leukemia, acute or chronic, is curable by any method known today, and, further, that it is doubtful that any one is in a position to authenticate a claim to have cured any case of Hodgkin's disease, lymphosarcoma or mycosis fungoides up to the present time. Nevertheless, leaving the acute leukemias and certain rapidly aggressive lymphomas out of the discussion, it is certain that many cases of chronic leukemia can be markedly palliated by one means or another, that promises of curability of some early cases of Hodgkin's disease and lymphosarcoma are evident in any large series and that in general early diagnosis and sufficient well

solar radiation has a regular periodicity of 6.6 days.^{32a} Adverse comment on the wisdom of such associations is made elsewhere.^{32a}

SUMMARY

Six cases of regularly periodic diseases have been studied; 3 characterized by fever and abdominal pain and 1 each by neutropenia, arthralgia and myasthenia. They are compared with other similar and different reported conditions, some synchronous with menstruation and others not. Most of them recur independently of any known natural rhythmic fluctuation and probably signify some obscure intrinsic cycle in both sexes. They may be a collection of unrelated medical curiosities, but if a common underlying cause can be discovered some or all of them may be grouped as a syndrome of periodic disease with different manifestations.

conceived early treatment of the chronic lymphomas will spell at least far superior results in terms of long control.

The possibility of curability of early Hodgkin's disease or lymphosarcoma depends primarily on whether these processes are of unicentric origin. Were they all of multicentric origin, naturally any treatment known today could be only palliative. If any of them arise, like carcinoma, in one focus, and spread only from that focus, then by eradication of the initial lesion or eradication of the disease while it remains confined to one region cure should be at least theoretically possible. The evidence for such a possibility is accumulating.

It has long been my experience, for example, in Hodgkin's disease, that outstanding among those cases with long survivals and long periods of freedom from disease are those in which the disease has been treated fairly aggressively while it is still early and localized. In particular have been noted those cases in which a single small node group, especially in the upper cervical region, has been excised surgically, the diagnosis has then been discovered on microscopic examination of the excised nodes, and then fairly aggressive irradiation has been promptly used over the operative field. Such observations are supported by further analysis of the patients treated at Memorial Hospital and by reports in the literature of the past decade. From Memorial Hospital Slaughter and Craver³ in 1942 reported 5 cases of Hodgkin's disease in which treatment was by surgical removal of the only nodal mass found, followed by local roentgen irradiation, with subsequent survival from five to eleven years. They referred to a report by Baker and Mann of England of two apparent cures of unilateral cervical Hodgkin's disease following surgical excision of all diseased tissue and postoperative roentgen therapy, the cures having lasted ten and twelve years, respectively. They referred also to 9 cases in the literature of gastric Hodgkin's disease treated by partial gastric resection. One patient had been well for four years and 1 for five years. In addition they referred to 1 case in the literature of resection of ileal Hodgkin's disease, with freedom of evidence of disease for five years before a recurrence was found in the small intestine.

An analysis of 196 cases of lymphosarcoma treated at Memorial Hospital, published in 1940 by Sugarbaker and Craver,⁴ indicated the possibility of improved results for localized lymphosarcoma by means of extirpative surgical procedures followed by local irradiation. They stated:

Twenty-five determinate patients were subjected to some extirpative surgical procedure: removal of an extranodal primary site (such as tonsil, breast or ileum) in eleven; node dissection in twelve, and removal of both an extranodal primary and an adjacent involved node group in two. With all but a few of these patients surgical treatment was shortly followed by local external irradiation given prophylactically. Of these patients 6 (24 per cent) are living five or more years later and all are apparently cured. A group of 62 patients on admission were considered to have a comparable amount of clinical disease, though in some instances not as anatomically accessible, and were treated by some form of radiation. Of these 16 per cent survived five years but only 8 per cent are apparently cured. The small size of these two groups prohibits any definite conclusions but certainly encourages further trial of a combined surgical and radiologic approach in these early cases.

As pointed out by Slaughter and Craver, if irradiation is used for early localized cases, in doses sufficient to be truly obliterative of the disease, the late result may in some cases be far worse than from a healed surgical wound, and, it may be added, worse than the late effects of local surgery followed by moderately heavy postoperative irradiation.

On the other hand, in recent years I have been somewhat disappointed at the early recurrences in some cases in which surgical treatment has been selected as the first mode of attack on localized Hodgkin's disease and lymphosarcoma. While on the one hand in some of these cases the disease has been deemed pre-operatively to be near the borderline of suitability for complete surgical removal and thus may have been too widespread to justify surgical removal, on the other hand consideration of the cellular nature of these lymphomatous processes and their proneness to early spread by way of the lymphatics naturally raises the question whether chances for cure might not after all have been enhanced by an immediate resort to heavy roentgen therapy, accepting its undesirable late effects of fibrosis, telangiectasis and radiation dermatitis.

At any rate, the principle seems sound that early localized Hodgkin's disease or lymphosarcoma offers the distinct possibility of better prognosis and perhaps even cure if treated adequately. I most decidedly do not agree with advocates of "the smallest quantity of irradiation that will effect resolution of the gross disease."⁵

TABLE 1.—Five Year Survivals in Lymphosarcoma

Stout (All Cases) ⁵	Craver (All Cases) ⁷	Catlin (Cases Involving Head and Neck) ⁶
23%	26.3%	52%

Catlin,⁶ analyzing 50 determinate cases of lymphosarcoma of the head and neck, treated at Memorial Hospital, found that the five year survival rate was 52 per cent, or double the rate for lymphosarcoma of all types as reported by me,⁷ 26.3 per cent, and as reported by Stout,⁵ 23 per cent. Twenty of Catlin's 50 lymphosarcomas of the head and neck arose in the tonsil and 11 in the "soft parts of the head and neck, including the nodes." The rest of the lymphosarcomas were distributed among various sites; namely, the nasal cavity, nasopharynx, paranasal sinuses, palate, orbit, tongue, gingiva and pharynx.

Table 1 summarizes the five year survival in Catlin's group of lymphosarcomas of the head and neck compared with the figures of Craver and those of Stout for the five year survival in all cases of lymphosarcoma.

Gall⁹ in 1943 published from the Massachusetts General Hospital a study of 48 cases of malignant lymphoma in which at an early operation the surgeon had been satisfied that he had removed all visible and palpable disease. Of 19 patients alive at the time of his report only 1 had shown evidence of malignant lymphoma at the time of the last examination, while the other 18 had been free of evidence of disease for at least three years. Despite several postoperative deaths, the average postoperative duration of Gall's

surgical group was five and two-tenths years, and the average total duration was six and nine-tenths years. These figures were, respectively, two and almost three times better than for cases in which treatment was by irradiation alone. (It should be pointed out here, however, that it may well be assumed that the cases selected as suitable for surgical procedures were by and large more favorable than those assigned to irradiation alone.)

Table 2 is a reproduction of Gall's table⁹ of the comparison of radical surgery with roentgen irradiation with respect to the survival of patients with malignant lymphoma.

More recently Hellwig¹⁰ reviewed 234 cases of malignant lymphoma treated from January 1925 to December 1945, and analyzed 130 cases with respect to the value of radical surgical procedures plus irradiation in selected cases.

TABLE 2.—Effect on Survival (Radical Surgery Versus Roentgenotherapy)

Type	Number of Cases	Range of Survival, Years	Median of Surgical Group, Years	Median of X-Ray Group, Years

		7-7-6 6-5-5-5		(coronary)
Follicular lymphoma.....	1	0	0	5 8/12
Plasmacytoma.....	1	6	0	0
Total.....	30			

Table 3 shows Hellwig's figures¹⁰ for five year survivals in 30 cases in which this treatment was used.

The longest duration noted by Hellwig was twenty years, following removal of a reticulocytoma of the tonsil.

Holmes and Schultz¹¹ reported from Massachusetts General Hospital on the radiation treatment of localized malignant lymphoma. They reviewed 500 cases, collecting those in which the patients were alive and apparently free of evidence of malignant lymphoma over five years following the last treatment, and in which the disease had been localized and had been treated only by irradiation. They found 15 such cases, the survivals in which ranged from five and eight-twelfths years to twenty-five and five-twelfths years.

Merner and Stenstrom¹² reported improved survival rates in Hodgkin's disease as a result of improved technics of irradiation.

10. Hellwig, C. A.: Malignant Lymphoma: The Value of Radical Surgery in Selected Cases, Surg., Gynec. & Obst. 84: 950-958 (May) 1947.

11. Holmes, G. W., and Schultz, M. D.: Radiation Treatment of Localized Malignant Lymphoma, New England J. Med. 235: 789-791 (Nov. 28) 1946.

12. Merner, T. B., and Stenstrom, K. W.: Roentgen Therapy in Hodgkin's Disease, Staff Meet., Bull. Univ. Minnesota 17: 262-277 (March 15) 1947.

Clearly, then, there does exist a promise of curability of early Hodgkin's disease and lymphosarcoma, provided treatment is sufficiently aggressive. It seems clear also that improved palliative results, in terms of relief of symptoms, duration of remissions and total length of survival, are obtainable by means of close follow-up for detection of lesions, whether obvious or obscure, and by means of well planned precise irradiation.⁷

For chronic leukemia in many cases a great deal can be accomplished in a palliative way by judicious irradiation, even though under present conditions one must accept incurability as the first premise.

For the acute leukemias and the relatively rare cases of rapidly progressive Hodgkin's disease and lymphosarcoma unfortunately at present there is little to offer that can produce more than fleeting benefit, although one may hope that further research in chemotherapy with newer nitrogen mustards or other compounds, or in application of radioactive isotopes, or perhaps in hormone therapy or some combination of such agents, may some day enable better control of these acute processes.

It is evident that, as in all cancer, hope for better control of lymphomas and leukemias rests on early diagnosis. In this field there are unique difficulties, familiar especially to pathologists and hematologists. How often the early biopsies in cases of Hodgkin's disease or lymphosarcoma fail to reveal the diagnosis and how often the early blood counts in cases of leukemia do not seem leukemic are only too well known to pathologists, hematologists and those clinicians who have extensive experience with these diseases. Nevertheless there are still far too many cases going undiagnosed far beyond the time when they could be diagnosed, and many of these are therefore being allowed to pass beyond the stage of possibility of cure or marked benefit.

Early diagnosis cannot wait for development of typical textbook symptoms and signs. Every early case may be said to be atypical in the textbook sense. This discussion therefore will avoid descriptions of typical fully developed cases, and will rather indicate certain of the more important early clues to diagnosis.

SOME EARLY SIGNS OF LYMPHOMAS AND LEUKEMIAS

Many patients later found to have Hodgkin's disease or lymphosarcoma give a history of having been reassured by the first physician consulted regarding an enlarged lymph node. It cannot be too strongly emphasized that any enlarged lymph node demands an immediate investigation. Entirely too frequent is the story of an enlarged node in the neck being passed off as the result of a cold or sore throat. Any supposedly inflammatory enlarged node that does not subside within three weeks should be regarded as a danger signal demanding complete investigation. Such investigation should include competent examination of the drainage territory of the node (for example, search of the nasopharynx, tonsil and adjacent areas for a possible primary lymphosarcoma in the case of an enlarged node in the upper cervical region), biopsy of the primary lesion if one is found, biopsy of the node if no primary lesion is found, a careful blood cell count and, of course, a complete physical examination for enlargements of other lymph nodes or of the spleen or liver. If, as often happens in early Hodgkin's disease or lymphosarcoma, no evidence of disease is found

except the enlarged node, which is reported after biopsy as chronic lymphadenitis or at any rate as failing to show evidence of any definite pathologic entity, and if then other nodes appear near the site of the originally enlarged one, there should not be undue delay before biopsy is made of another node which seems on palpation to be representative of something abnormal.

Nodes in the thyroid region are often mistaken for goiter. Careful palpation will usually differentiate between a goiter and enlargement of lymph nodes at the base of the neck.

Cough, substernal pressure, fulness at the base of the neck and puffiness of the eyes on arising, wheezing and dyspnea are symptoms any or all of which should indicate the need for a competent straight postero-anterior and straight lateral roentgenogram of the chest and, if necessary, oblique roentgenograms and tomograms to exclude a mediastinal tumor, which might be Hodgkin's disease or lymphosarcoma, among other possibilities. In such cases significant nodes lying at the base of the neck, especially between the two lower insertions of the sternocleidomastoid muscle, are often overlooked because of failure of careful palpation with a light pressure. A gentle palpation with moistened fingers may disclose a node that was missed by rough palpation.

Lymphosarcoma of the tonsil is often overlooked for a long time. Any peculiar irregularity or firm rubbery part of a tonsil should be regarded with suspicion. Lymphosarcoma of the tonsil seldom ulcerates in an early stage. It would be a good policy to have all tonsils that are removed, especially from patients beyond the age of puberty, subjected to examination by a pathologist.

A solitary lump in a woman's breast may not be a cyst, fibroadenoma or mammary carcinoma, but may be the initial manifestation of lymphosarcoma.

In the skin, especially of the scalp, a slightly thickened pink or purplish plaque may be the first evidence of lymphosarcoma. Some of these cutaneous lymphosarcomas can be kept under control for years by irradiation, while others rapidly generalize and prove to be aggressive rapidly fatal processes.

A thickening in and about the lacrimal gland or the conjunctiva, even though reported on biopsy or surgical removal as a benign orbital lymphoma, may in from a few months to a few years be found to have been the first indication of a generalizing form of lymphosarcoma.

A change in bowel habit or other gastrointestinal symptoms may be the first sign of a localized lymphosarcoma or Hodgkin's disease of the alimentary tube, and some of these have been successfully removed surgically or caused to regress by radiation, with subsequent long survival.

Localized reticulum cell sarcoma of bone responds well to adequate irradiation; hence symptoms referable to a bone call for roentgenographic study, and if such study reveals a bone lesion biopsy should be done.

The differential white blood cell count may be the first indication of leukemia.

Chronic lymphatic leukemia may produce, as its first manifestation, any of the findings just described as suggestive of Hodgkin's disease or lymphosarcoma. Therefore it is necessary to look at the patient as a whole in considering the differential diagnosis, looking for abnormalities in all the lymph node-bearing areas, for enlargement of the spleen and liver, for changes in the blood count and, if it seems indicated, for

changes in the marrow. What seems on biopsy to be lymphosarcoma may prove to be part of a leukemic process, either then or later.

In addition there are certain other symptoms and signs that may suggest leukemia.

In chronic myeloid leukemia the patient may carry a large spleen for some months without being aware of its presence, but aware only that he has "indigestion," i. e. distress in the upper part of the abdomen.

The leukemic patient commonly has had a tendency to have black and blue marks on slight bruising for many years. His gums may bleed readily, and sometimes the first alarming symptom is prolonged bleeding after extraction of a tooth or after tonsillectomy. Routine blood cell counts preceding tonsillectomy do not rule out the possibility of leukemia, and any history of easy bruising or other bleeding tendency and of fatigue or pallor should indicate the need for more detailed hematologic investigation before tonsillectomy is done. Anemia, an enlarged spleen and what might be considered a low grade leukemic blood cell count—for example, 20,000 white blood cells with a few myelocytes—should particularly raise suspicion of osteosclerotic anemia or leukoerythroblastic anemia, and there should be further investigation by means of roentgenograms of pelvis and long bones, search for a marrow-invading tumor process and sternal marrow biopsy before the diagnosis of leukemia is accepted. In such cases the enlarged spleen may be regarded as a protective mechanism, caused by the need for extramedullary hemopoiesis resulting from replacement of the bone marrow by osteosclerosis or metastatic tumor.

PREVENTION

No extensive fund of knowledge exists regarding prevention of lymphomas and leukemias. There are a few facts and some impressions that may be reviewed.

Exposure to such solvents as benzene may produce leukemia, or in fact almost any sort of derangement of the hemopoietic system. Cases of lymphosarcoma and Hodgkin's disease have been seen in which there has been a long history of exposure to solvents.

It seems fairly clear that repeated exposure to radiation such as roentgen rays and gamma rays of radium may lead to the development of leukemia.

In children with acute leukemia it is so common nowadays to obtain a history of repeated use of sulfonamide drugs for minor infections of the respiratory tract that, with the knowledge of their ability to derange the hemopoietic system and despite the lack of proof that acute leukemia is of any more frequent occurrence now than before the advent of sulfonamide drugs, it is difficult to avoid speculation regarding the individual cases as to whether the sulfonamide compound may have been responsible.

In Hodgkin's disease it may commonly be noted that onset and exacerbations seem associated with the common cold. In some cases of lymphosarcoma of the pharynx and cervical nodes there is a history of repeated or chronic infection of the upper respiratory tract. In some other cases of lymphosarcoma there has been a history of infection in the drainage territory of the nodes initially attacked by lymphosarcoma.

Inquiry into the contact history of patients with Hodgkin's disease will disclose not a few who have had rather close association with a case of active tuberculosis within a few years of the onset of Hodgkin's disease.

At Memorial Hospital in the past few years my colleagues and I have seen several cases presenting

evidence suggesting transitions between Boeck's sarcoïd and Hodgkin's disease or lymphosarcoma.

Allergic manifestations are frequent in Hodgkin's disease. There is in many such cases a history of allergy for years prior to the apparent onset of the Hodgkin process. Some cases have been observed in which Hodgkin's disease became evident not long after a series of inoculations of some sort, as for hay fever. To these observations may be added the frequency of urticaria in the early stages of Hodgkin's disease, the itching and rashes so common in these cases and the eosinophilia so characteristic of the histology of Hodgkin's nodes.

When one commonly finds that 2 siblings have chronic lymphatic leukemia or when one obtains histologic proof that 3 siblings have died of Hodgkin's disease, one is naturally inclined to place some credence in heredity of these diseases.

In adults one gains the impression that chronic lymphatic leukemia and lymphosarcoma seem in many cases to arise at the time of the female or male climacteric.

It seems best merely to state these observations, without attempting therefrom to formulate any set of rules for prevention of lymphomas or leukemias.

METHODS OF TREATMENT

Chemotherapy in the form of nitrogen mustards and irradiation of the whole body by the internal method available from such radioactive isotopes as those of phosphorus, sodium, manganese or gold have been so publicized that many lay persons and some practitioners have gained the impression that these agents afford the methods of choice in the treatment of lymphomas and leukemias. It should be emphasized that up to now these agents have afforded only palliative effects.

Nitrogen mustards, of which the one most commonly used is the compound methyl-bis (2-chloroethyl) amine hydrochloride, are useful for palliative effects particularly in generalized Hodgkin's disease, to a less extent in generalized lymphosarcoma and in lympholeukosarcoma and to a considerably less extent in chronic leukemia.

Some of the newer nitrogen mustards have shown transitory beneficial effects in acute leukemia. Even in the best field so far found for nitrogen mustard therapy, that is, in Hodgkin's disease, while the remissions may be striking, they are unfortunately disappointingly brief in many instances.

It is clear that these toxic constitutional agents have little or no place in the treatment of early localized Hodgkin's disease or lymphosarcoma. For such cases adequate local roentgen therapy remains the treatment of choice, except perhaps in those cases that would lend themselves to radical surgical procedures, which should probably be followed by moderately heavy local postoperative roentgen therapy.

It is often asked what dose of roentgen rays constitutes adequate treatment of a localized lymphoma. That dose has not been defined. One thing that is certain is that it is nearly always far more than just enough to cause regression. It probably should be about the maximum dose that can be tolerated by the skin overlying the disease, and probably should be given in fractional increments. What fraction of the total dose each increment should be quite possibly varies from case to case, depending on various factors such as size of field and radiosensitivity of the disease in each particular case. Currently in a case of unilateral

involvement of cervical lymph nodes we apply at Memorial Hospital 200 r of 250 kilovolt roentgen therapy at 50 cm. target-skin distance, filtered through 1.5 mm. of copper, every second day to a total of 2,000 to 2,400 r, measured in air. Perhaps this dose should be increased in those cases in which, by the time it has been administered, there is still no evidence of spread of the disease to other regions.

In localized lymphosarcoma of an external node group, as in the femoral triangle, we give 300 r with the same factors as those just mentioned, every second day to a total of 2,400 r to 3,000 r measured in air, and perhaps should give more. Some cases do show local recurrence following these doses.

Review of cases in which treatment was by total body external irradiation at extremely low intensity (0.8 to 1.6 r per hour for twelve to eighteen hours a day) strongly suggests that a moderate dose, 75 to 125 r measured in air, of whole body irradiation following the local irradiation will unpredictably in some cases of Hodgkin's disease or lymphosarcoma confer a longer freedom from relapse than would have been expected, but the unpredictability of this result and the deleterious effects in some cases are deterrents to routine application of this method.

Even when Hodgkin's disease or lymphosarcoma begins to generalize, by and large roentgen irradiation is a more effective agent than any of the nitrogen mustards that have been tried up to the present. As stated before, the chief usefulness of the nitrogen mustards available now has been for palliation in the generalized cases, and that palliation is often of too brief duration.

The radioactive isotopes of phosphorus and sodium may palliate chronic leukemia, but are of relatively less effect in lymphosarcoma and seldom of any great benefit in Hodgkin's disease.

Urethane may produce remission of chronic leukemia, usually only after administration for a few to several weeks, and in only about one fourth to one third of the cases.

Leukemia is so variable a disease that it is impossible to formulate a general plan of treatment.

The typical case of chronic myeloid leukemia, presenting a blood and marrow picture in conformity with that diagnosis and showing on physical examination essentially no other abnormality than an enlarged spleen, will usually do well following irradiation of the spleen with three or four times 100 r anteriorly and posteriorly (250 kilovolts, 70 cm. distance, filtered through 1.5 mm. of copper).

In the typical case of chronic lymphatic leukemia presenting a blood and marrow picture in conformity and moderate enlargement of external lymph nodes, together with moderate splenohepatomegaly, there may be considerable benefit from a course of 200 r to 300 r once around to each of the external lymph node-bearing regions.

Beyond these sketchy statements concerning the early radiation therapy of chronic leukemia it seems outside the scope of this article to venture. Many exceptions occur. Cases of chronic myeloid leukemia are seen showing no enlargement of the spleen, and there are cases of chronic lymphatic leukemia with no perceptible lymphadenopathy or ~~hepatomegaly~~. Some patients with chronic leukemia ~~may~~ ^{may} ~~be~~ ^{case} reasonably well without treatment for some months or years. Every case calls for individualization.

In summary, all treatment known for leukemia today is at best merely palliative, but early diagnosis, close

observation and the exercise of good judgment in applying available means of treatment or, in some instances, withholding specific treatment, depending on the individual circumstances, may spell markedly improved palliation. The special pleas of this article are (1) for recognition of the possibility of better control of Hodgkin's disease and lymphosarcoma that can result from early diagnosis, adequate early therapy and close follow-up for detection of lesions so as to permit prompt application of appropriate therapy and (2) for recognition of the evidence presented from various sources that some cases, at least, of Hodgkin's disease and lymphosarcoma seem to be of unicentric origin and therefore should be curable if recognized and adequately treated in their earliest stage.

Clinical Notes, Suggestions and New Instruments

TREATMENT OF TUBERCULOUS ULCER OF THE TONGUE WITH STREPTOMYCIN

HENRY WOLFER, M.D.
IRVING HIRSHLEIFER, M.D.
and
RAYMOND SHAPIRO, D.D.S., M.D.
Brooklyn

Lingual tuberculosis is not frequent.¹ Up to 1945 there were only slightly more than 400 reported cases,² of which the largest number were found in patients over 40 years of age. Of this group a preponderance were found in the fifth decade.^{1b} Males are more often affected than females, and Negroes infrequently. The infrequency of tuberculous ulcers of the tongue may be due to the vascularity of the organ, constant mechanical action of the tongue, possible germicidal action of the glandular secretions,^{1a} and the general resistance of striated muscle to bacterial invasion.²

Tuberculosis of the tongue is caused by the lodgment of tubercle bacilli in the tissue of the tongue and their subsequent proliferation. Theoretically the bacilli may reach the tongue by hematogenous spread, lymphatic spread, direct extension or actual contact. Primary tuberculosis of the tongue if existing is rare.^{1a} It is usually secondary to tuberculosis in other parts of the body, generally the lungs.

In order of frequency tuberculous ulcers of the tongue have been reported³ on the following sites: edge, base, tip and dorsum of the tongue. Valtan⁴ found the dorsum of the tongue the most commonly affected surface.

Titcher² listed five types of tuberculosis of the tongue: (1) ulcer, (2) fissure, (3) granulomas, (4) tuberculomas and (5) glossitis, with the tuberculous ulcer most common. The granulomas are vascular nodular elevations, soft or hard in consistency. The tuberculomas are painless nodules in the deeper tissues.⁴ The typical ulcer has sinuous, undermined edges,^{3b} is of irregular outline and is covered with a grayish exudate.^{4a} It lacks the induration of a cancerous lesion.⁵ Histologically it is always characterized, no matter what its final

physical configuration may be, with the usual central caseation, the occurrence of giant cells, connective tissue proliferation, with at times round cell infiltration, and occasionally formation of abscess.^{3b} These ulcers must be differentiated from syphilitic ulcers, carcinomatous ulcers and traumatic ulcers.⁶ Pathologic examination and serologic tests are necessary for differentiation.

The use of streptomycin for the treatment of tuberculous ulcer of the tongue was prompted by the favorable response in other selected cases of tuberculous infections to the use of this substance.⁷

REPORT OF CASE

The patient was a white man aged 49 who was admitted to the hospital March 10, 1947 because of a recalcitrant ulcer of the tongue. He remembered sticking his tongue with a fish bone about the third week in July 1946. The following day a bleb appeared at the traumatized site which soon ruptured. This was followed by an open wound which became progressively larger. There was not much pain associated with the lesion at this time. A biopsy as performed about a month

Fig. 1.—Photomicrograph of base of ulcer.

later; an ulceration of the tongue was reported favoring a diagnosis of tuberculosis. The blood Mazzini reaction was negative for syphilis and there was no evidence of carcinoma. He was then treated with a white pastelike substance the nature of which is unknown. The lesion became progressively larger and more painful until his present hospital admission.

The patient first became aware that he had pulmonary tuberculosis in 1931, at which time there were diagnostic roentgenologic findings and a positive sputum. He was hospitalized for the first six months in 1940. He states that he had a 'great

deal of hoarseness at this time, but the hospital records reveal evidence of an active tuberculous process in his lungs and at no other site. All examinations of his sputum indicated the presence of acid-fast bacilli during this period.

On admission a general physical examination of the patient revealed nothing significant aside from widespread crepitant rales throughout both pulmonary fields and the lingual abnormalities. There was an ulcerative lesion situated on the central portion of the dorsum of the tongue 1 cm. wide and 1.5 cm. long of an elliptic configuration. The edges were ragged and overlapping and there were papillomatous excrescences on the floor of the lesion, giving it a worm-eaten appearance. The lesion was filled with a dirty, yellowish gray exudate. There was excessive salivation. A roentgenogram of the thorax revealed bilateral, caseous pneumonic tuberculosis of both upper pulmonary fields with the presence of numerous cavities. Multiple examinations of the sputum indicated the presence of acid-fast bacilli. Wassermann examinations of the blood were negative in result on two occasions. A microscopic examination of excised sections of the ulcer revealed acute and chronic inflammatory tissue in multiple areas. In one section several giant cells with oval vesicular peripheral nuclei were seen. There were also tubercles which showed the presence of caseation. The histologic diagnosis was granuloma of the tongue, probably tuberculous (fig. 1).

On March 17, treatment with 1 Gm. of streptomycin was begun daily. It was given intramuscularly in eight divided

Fig. 2.—Gross appearance of ulcer. A, before therapy. B, after epithelization was complete.

doses at three hour intervals. In ten days a great improvement in the patient's appetite and sleeping habits and a definite feeling of well-being were noted. The edges of the ulcer appeared to be less ragged, the base appeared cleaner and some epithelization was seen. On March 30, the total daily dose of streptomycin was divided in nine parts. The additional fraction was used for local infiltration of the ulcer itself. With this new method of administering the antibiotic, further improvement in the appearance of the ulcer was not noticeable. Therefore on April 16 the original method of therapy was resumed and local infiltration was discontinued. After this change in treatment the lesion healed rapidly. By the first of June complete epithelization had taken place. A total of 75 Gm. of streptomycin had been given. The patient gained 8 pounds (3.6 Kg.) during the course of therapy. Roentgenograms of his thorax showed no change and his sputum remained positive for acid-fast bacilli. His course was followed by photographs taken March 13 and June 6 (fig. 2).

COMMENT

This is the first case of a tuberculous ulcer of the tongue treated with streptomycin to be reported in the literature.

We assume that streptomycin was responsible for the healing, since the lesion became progressively worse without any remissions prior to our treatment. We believe that the action of the drug was local, since the patient's sputum remained positive for acid-fast bacilli and roentgenograms of his chest during the course of treatment exhibited no changes.

The ulcer responded to the parenteral administration of streptomycin but not to its local infiltration. It is suggested that this was due to the granulomatous nature of the lesion.

SUMMARY

A case of tuberculous ulcer of the tongue successfully treated with streptomycin is reported.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The Council recently published in *THE JOURNAL* (Nov. 15, 1947, p. 714) a report on Homologous Serum Jaundice. This statement was prepared by the Committee on Blood and Blood Derivatives of the Advisory Board on Health Services of the American National Red Cross. The chairman of this committee, Dr. Charles A. Jancway, has supplied to the Council additional information on human serum albumin. The data are so important that a résumé has been adopted by the Council for publication.

Salt-poor normal human serum albumin is now available in limited quantities only from one commercial source; it is necessarily expensive, because nearly four bleedings are needed to obtain 25 Gm. of albumin and because it is necessary to maintain blood collection stations, to pay donors and to meet high standards of processing on a relatively small scale. It seems probable that sufficient blood to meet the actual need and to provide such derivatives as serum albumin, antihemophilic globulin, fibrin film and immune serum globulin at reasonable cost can only be procured from volunteer donors. Public programs for the collection and processing of blood by cooperative effort between the Red Cross and the state department of health have already been set up in several states. In at least two of these, Massachusetts and Michigan, it is probable that serum albumin will be available to physicians in the not too distant future. The recent announcement by the American National Red Cross that it has adopted as one of its major objectives a national blood program, based on the collection of blood from volunteer donors and the distribution of blood and its derivatives without charge for the product to physicians of the United States and its territories, indicates that serum albumin will be more generally available in due time. However, this undertaking will probably require at least five years to become fully effective. Vice Admiral Ross T. McIntire, U.S.N., retired, former Surgeon General of the Navy, has agreed to serve as its administrator. As head of the medical department of the Navy during the war, he was closely associated with the development of the combined Red Cross-Army-Navy blood program. The American Red Cross has formed an Advisory Board on Health Services, consisting of over a hundred authorities in various phases of medicine, public health and allied fields. This board is organized in a series of committees, one of which is the Committee on Blood and Blood Derivatives.

Because there was no opportunity during the war to determine the value of human serum albumin in clinical conditions other than shock in which it might be expected to have some therapeutic effect, a limited supply of serum albumin has been salvaged from unsatisfactory lots of surplus dried plasma and distributed by the American Red Cross to a group of investigators in many of the country's leading medical centers for a variety of clinical investigations. It is expected that the report of this group, whose studies began only this spring, will ultimately be published and will answer many questions concerning the optimal uses of serum albumin in various branches of medicine.

The Council expresses its appreciation of the help provided by Dr. Jancway and the other members of the committee in supplying the data in the Council report.

AUSTIN SMITH, M.D., Secretary.

HUMAN SERUM ALBUMIN IN NEPHROSIS

Methods were developed during the war for separation of the various functional components of human plasma into fractions, in each of which specific activities are concentrated in stable and therapeutically useful form. This development was stimulated by the urgent need of the United States Navy for a safe and effective blood substitute, which would be less bulky to transport and more convenient to use than dried plasma under the difficulties that characterized many of the landing operations in the Pacific. The safety, ease of administration and range of effectiveness of serum albumin as a blood substitute in the treatment of shock following trauma, hemorrhage, operations and burns have been amply tested by clinical investigations in this country and by experience in the field. Likewise, the limitations of both plasma and serum albumin in comparison with whole blood are well recognized. If whole blood were to become increasingly available, the necessity for using substitutes (plasma or serum albumin) rather than blood itself in the resuscitation therapy of acute surgical and traumatic cases would diminish.

There are, however, other clinical conditions in which a solution rich in osmotically active protein and poor in sodium might be particularly useful. The original solution of normal human serum albumin, which was developed for the Navy, contained 25 per cent albumin in a diluent of sodium salts in twice isotonic concentration. The finding that the thermal stability of the solution could be definitely enhanced by using 0.04 molar acetyl tryptophane as the diluent made possible the development of salt-poor human serum albumin. One hundred cubic centimeters of this solution (25 Gm. of human serum albumin) contains approximately 0.35 to 0.4 Gm. of sodium as compared to 0.9 to 1.0 Gm. in the original solution and 2.1 Gm. in an osmotically equivalent amount (500 cc.) of citrated plasma. The stability of this material is such that it has been possible to heat the containers for ten hours at 60 C. as a final step in the process, a step which has been shown to inactivate a strain of the virus of homologous serum jaundice and which has made possible the omission of mercurial preservatives. Since no antibacterial agent is present, the solution in each container should be used on one occasion only.

A few preliminary clinical studies of the use of salt-poor normal human serum albumin in a small number of cases of hypoalbuminemia due to malnutrition, infection, chronic hepatitis, cirrhosis of the liver and the nephrotic syndrome have appeared in the literature. It is in those cases, particularly common in childhood, of intractable and massive edema associated with severe proteinuria due either to lipoid nephrosis or chronic glomerulonephritis that physicians, perhaps goaded by desperate parents, are most apt to turn to serum albumin as a last resort. This has been encouraged by at least one published report and by newspaper publicity.

There is no doubt that salt-poor human serum albumin is effective in relieving edema in a certain number of cases. In order to obtain such an effect large doses must be administered intravenously every day for considerable periods of time. In most cases, a large proportion of the injected albumin can be recovered in the urine and only a small proportion is retained, so that it is difficult to produce any substantial elevation of the concentration of serum albumin. Fear that such massive proteinuria may in itself lead to kidney damage has been expressed by certain workers, but definite evidence for or against this hypothesis has not been reported. The starting doses which have been suggested by those most familiar with the problem are roughly 12.5 Gm. daily in children under 3 years of age, 25 Gm. daily in children aged 3 to 12 years and 50 Gm. daily in adolescents and adults. If such a dose is not effective in several days, it may be increased by 50 to 100 per cent and continued for several days more. Albumin is preferably administered as 25 per cent solution at a rate sufficient to produce a considerable fall in hemoglobin concentration or hematocrit reading, indicating an increase in plasma volume due to the osmotic activity of the albumin. In patients with cardiovascular disease concentrated albumin should be administered cautiously, because the increased blood volume may possibly precipitate pulmonary edema. It should be stressed that there is no evidence yet to prove that serum albumin is more than a useful diuretic,

producing temporary relief from edema in these cases. The protection of these patients from the infections to which they are so susceptible and the provision of adequate calories and protein with an absolute minimum of salt are still the mainstays of treatment. Physicians should remember that this condition is extremely variable in its course, the edema often undergoing unexplained spontaneous remissions and exacerbations; its ultimate prognosis has improved considerably since the introduction of sulfonamide drugs and penicillin as therapy for the bacteremia and peritonitis which so often proved fatal in the past. It is to be hoped that the investigations now under way will ultimately provide clearcut evidence for the practitioner on the place of serum albumin in the treatment of patients with edema associated with renal disease.

REPORT OF THE COUNCIL

The Council has authorized publication of the following statements.

AUSTIN SMITH, M.D., *Secretary.*

STATICIN AND CARONAMIDE, PROTECTED AND GENERIC TERMS FOR 4'CARBOXY-PHENYL-METHANESULFONANILIDE

Sharp & Dohme, Inc., informed the Council that it had under clinical evaluation a new compound designated chemically as 4'carboxy-phenylmethanesulfonanilide and asked the Council to recognize protected and nonprotected names for the drug. After considerable correspondence with the firm, the designation "staticin" (suggested by the firm) was arrived at as the trade name and caronamide (also suggested by the firm) as the generic designation.

Subsequently the firm asked recognition of a trade name and generic name for a suspension of "staticin," suggesting "cremostaticin" as the protected name and caronamide suspension as the generic name. At that time the firm asked that the term "penalev" be recognized as an alternative designation for "staticin" in accordance with its policy of having a second or alternate trade name for its products. The Council found no objection to this designation.

The Council voted therefore to recognize "staticin" (stat'-i-cin) as the protected name and caronamide (ca-ron'-amide) as the generic name for 4'carboxy-phenylmethanesulfonanilide and to recognize "cremostaticin" (crem-o-stat'-i-cin) and caronamide suspension as protected and generic designations, respectively, for a suspension of the drug.

CHLORGUANIDE HYDROCHLORIDE, GENERIC TERM FOR CHLOROPHENYL ISOPROPYL BIGUANIDE HYDROCHLORIDE

The Council has considered the desirability of recognizing a brief generic term for the antimalarial compound, chlorophenyl isopropyl biguanide hydrochloride, known under a British trademark as "paludrine hydrochloride." As a result of its deliberations, the Council voted to recognize the term, chlorguanide hydrochloride, as the generic designation for this agent and further voted to recognize "paludrine hydrochloride" as the protected name provided it is so presented by any manufacturer.

ARSENAMIDE, GENERIC TERM FOR p-(bis-[carboxy-methylmercapto]-arsino)-benzamide

Attention of the Council was called to the desirability of recognition of an appropriate generic name for p-(bis-[carboxy-methylmercapto]-arsino)-benzamide. The term arsenamide was suggested by Drs. G. F. Otto and T. H. Maren of the Department of Parasitology, School of Hygiene and Public Health, and Department of Pharmacology and Experimental Therapeutics, School of Medicine, Johns Hopkins University, Baltimore. These investigators had studied the chemistry and compound. As a result of its consideration, the Council voted to recognize the term arsenamide (ar-sen'-am-ide) as the generic designation for p-(bis-[carboxy-methylmercapto]-arsino)-benzamide.

SATURDAY, JANUARY 24, 1948

DEATHS OF PHYSICIANS IN 1947

THE JOURNAL during 1947 published the obituaries of 3,040 physicians as compared to 3,358 in 1946 and 2,962 in 1945. The American Medical Directory Report Service received during 1947 reports of deaths of 3,568 physicians in the United States and possessions, or 528 more than those published.

The average age of the 3,040 whose obituaries were published was 66.7 years as compared to 66.1 in 1946 and 65.3 in 1945. Four physicians died between the ages of 20 and 24, 65 between 30 and 34, 65 between 35 and 39, 75 between 40 and 44, 120 between 45 and 49, 170 between 50 and 54, 249 between 55 and 59, 321 between 60 and 64, 480 between 65 and 69, 548 between 70 and 74, 455 between 75 and 79, 252 between 80 and 84, 143 between 85 and 89, 58 between 90 and 94, 8 between 95 and 100 and 2 lived to be more than 100 years old. The number by age groups compares favorably with the previous year except in the 30 to 34 age group, where 43 were recorded during 1946 as compared to 65 during 1947.

Causes.—Both the primary causes of death and contributing factors are included in the following figures. Diseases of the heart continued as the leading cause of death among physicians, with a total of 1,406 recorded. Coronary embolism, thrombosis and occlusion led the heart group with 677 as compared to 738 for 1946; four of these were 30 to 34 years of age, 14 were 35 to 39, 16 were 40 to 44 and 28 were 45 to 49. In addition, angina pectoris and other coronary conditions were reported as causing 125 deaths, an increase of 19 over the previous year. An increase was shown for diseases of the myocardium and pericardium from 123 to 152 and for other diseases of the heart from 375 to 432. There was a notable decrease in chronic valvular disease and rheumatic heart disease from 28 in 1946 to 10 in 1947.

Cerebral hemorrhage, thrombosis and embolism took the lives of 384 physicians, pulmonary embolism 11 and other embolism and thrombosis 21. Arteriosclerosis caused 252 deaths, an increase of 67 over 1946. Hypertension, hypertensive cardiovascular disease and cardio-

renal disease contributed to 162 deaths, an increase of 71 over 1946. Aneurysm accounted for 20 deaths, and other diseases of the circulatory system for 16. Hodgkin's disease and leukemia caused 27 deaths, pernicious anemia 4 and other diseases of the blood 5.

Diseases of the respiratory system caused 168 deaths, of which 57 were due to bronchopneumonia, bronchiectasis or emphysema, 16 to hypostatic pneumonia, 13 to lobar pneumonia, 2 to atypical or virus pneumonia and 68 to pneumonia of unspecified type. Pulmonary tuberculosis caused 16 deaths, other types of tuberculosis 7, bronchitis and pleurisy 4 and asthma 2.

Of the 319 deaths attributed to cancer and tumors 100 were from cancer of the gastrointestinal tract, 61 from cancer of the genitourinary tract, 3 each from cancer of the brain and nervous system and cancer of the skin, 1 from cancer of the lip and 104 from cancer or tumor of unspecified organs; 10 of the deaths due to cancer were caused by lymphosarcomas. One physician in the 45 to 49 age group died of melanoma, 1 in the 65 to 69 group of cancer of the male breast and 3 of hypernephroma.

Of the total of 49 deaths from diseases of the nervous system, 11 were due to encephalitis, 10 to Parkinson's disease, 7 each to dementia paralytica and other diseases of the brain, 6 to other diseases of the spinal cord, 2 to meningitis and 1 to locomotor ataxia.

Diseases of the digestive system accounted for 132 deaths, of which 27 were due to cirrhosis of the liver, 15 to diseases of the gallbladder and bile ducts, 13 to peptic ulcer, 11 to peritonitis, 9 to other diseases of the liver, 7 to hernia, 4 to appendicitis and 46 to other diseases of the gastrointestinal tract.

Chronic nephritis or uremia was the commonest cause of death among diseases of the genitourinary system, with 109 recorded. Diseases of the prostate was next with 20, followed by acute nephritis with 18 and other diseases of the genitourinary tract, 9. One physician died of sulfadiazine anuria.

Of the deaths attributed to certain other infectious diseases, influenza was responsible for 7, poliomyelitis 3, mumps 2 and bacteremia or septicemia 1.

Diseases of the bones contributed to 3 deaths, 1 of which was due to Paget's disease.

Other causes of death among physicians during 1947 were diabetes 44, arthritis 9, multiple myeloma 8, exfoliative dermatitis and alcoholism 3 each, splenomegaly and other diseases of the spleen and rheumatic fever 2 each, and 1 each to heat stroke, diseases of the thyroid, Addison's disease, acute leukemic reticulo-endotheliosis, subarachnoid hemorrhage, exposure and malnutrition.

Twenty-four physicians in the total number published died following operations. In 51 cases the cause of death was not obtained.

Suicides and Homicides.—Forty suicides were recorded last year as compared to 55 during 1946. Seventeen were attributed to bullet wounds, 7 to

poisoning, 4 to cut arteries, 3 to drugs, 2 each to hanging and gas and 1 each to anesthesia, jumping and burning to death; 2 methods were unspecified. The 5 homicides reported were due to shooting. Two physicians were killed by unknown assailants, 1 in a holdup, 1 by cattle thieves and 1 by a patient.

Accidental Deaths.—Of the 159 accidental deaths, 68 involved automobiles; 5 were collisions with trains and 1 a collision with a streetcar. Thirteen died in airplane crashes and 9 were drowned, 1 when his fishing boat went over a dam; 6 died of burns. One physician was killed when his tractor toppled down an embankment, and 2 died in the Wynecoff Hotel fire in Atlanta, Ga.

Association Officers.—Among the decedents were 2 former vice presidents of the American Medical Association and 1 trustee. Of the 4 council members, 1 had been a chairman. Eight had been section officers, 2 had served on the judicial council and 30 had been members of the House of Delegates. In the total number were 34 who had been presidents of state medical societies and 1 a president-elect; 221 were or had been presidents of county medical societies as compared to 216 for 1946.

Miscellaneous Positions.—Among the decedents 239 had been teachers in medical schools. Ten had been deans, and 167 were professors as compared to 122 in 1946. One was a member of the Federation of State Medical Boards, 1 each served on the National Board of Medical Examiners and the Basic Science Board, 27 on the Board of Medical Examiners and 106 on boards of education. There were 193 health officers, 102 members of boards of health, 18 city councilmen, 53 coroners, 41 mayors, 30 pharmacists, 25 authors, 22 legislators, 20 editors, 18 bank presidents, 9 missionaries, 9 police physicians or surgeons, 4 postmasters, village presidents and dentists, respectively, and 2 sheriffs. One had been a lawyer and 1 a justice of the peace.

Government Service.—Of the decedents who had been in the military forces, 7 had served on the Mexican Border, 1 in the Boer War, 2 in the Boxer Rebellion, 1 in the Civil War, 2 in the Philippine Insurrection, 64 in the Spanish American War, 603 during World War I, 175 in World War II and an additional 117 on draft boards. One had been a contract surgeon for the U. S. Army, 1 a consultant to the Surgeon General of the Army and to the Secretary of War, 1 had served on a special commission of the Secretary of War and 2 were on procurement and assignment duty. Nine had served in the National Guard.

Twenty-four physicians had been in U. S. Public Health Service, 21 in the Public Health Service Reserve, 13 in the Indian Service and 10 with the Veterans Administration.

Killed in Action.—Reports of physicians killed in action and dying in military service during World

War II continued to be cleared through official military channels. Thirty-three were reported killed in action as compared to 40 in 1946. Nine died in the South China Sea when the Japanese ship on which they were being transported as prisoners to Japan was sunk Oct. 24, 1944. Other locations of death listed were in the Philippines 4, the Pacific 4, aboard ship 4, 2 each in Germany and Okinawa, 1 each in Dutch New Guinea, Iwo Jima, Guadalcanal, Java, Netherlands and North Africa. Seven of those killed in action were between the ages of 25 and 29, 19 between 30 and 34, 4 between 35 and 39 and 3 between 45 and 49.

Died While in Military Service.—Thirty-four other physicians died while in military service as compared to 128 in 1946. Ten died in accidents, 4 of which involved airplanes and 2 automobiles. One died at 24 years of age, 9 each between 25 and 29 and 30 and 34, 3 between 35 and 39, 4 between 40 and 44, 3 between 45 and 49, 1 between 50 and 54, 3 between 55 and 59 and 1 between 60 and 64.

The average age of the physicians killed in action was 31.9 years as compared to 35.2 in 1946, and of those who died in military service 37.1 years as compared to 42.8 for 1946. Deducting the military deaths, the average age at death of the remaining physicians is 67.5 years for 1947, the same as for 1946.

This brings the total deaths of physicians recorded in THE JOURNAL since the outbreak of World War II on Dec. 7, 1941 to 290 killed in action and 535 who died while in military service, or a total of 825 military deaths. Others are in process of being cleared through official military channels and await publication.

RABIES DIAGNOSED BY INOCULATION OF SALIVA INTO ANIMALS

A boy, aged 13 months and previously well, developed fever, became disoriented and refused food. His hands moved constantly and he would neither sit nor stand. Stiffness of the neck or back was not present, and the reflexes were not abnormal. The pupils reacted to light and one was slightly larger than the other. Impairment of hearing or speech did not occur. Five weeks previously the patient fell on a toy while playing in his pen and sustained a laceration of the upper lip which required several sutures. The wound was healed on admission to the hospital, and the reddened scar was not indurated. The rectal temperature was 103 F., the pulse rate 100, the blood pressure 120 systolic and 80 diastolic; otherwise the examination revealed nothing extraordinary. The leukocyte count was 7,200 with 40 per cent polymorphonuclears and 58 per cent lymphocytes. The hemoglobin was 12 Gm. The tuberculin test was negative. The cerebrospinal fluid, obtained under pressure of 200 mm. of water, contained 13 mononuclear cells per cubic millimeter and a normal amount of sugar; it was free from globulin. Cultures of the cerebrospinal fluid and of the blood were nega-

tive. During the first day in the hospital the child apparently did not have pain and did not recognize his parents. Hyperexcitability with muscular twitching and labored respiration alternating with brief periods of sleep characterized the third day. At times he cried out. These alternating periods of muscular excitability and sleep continued for several days. Respiratory difficulty was present only at periods of spasm. The pulse occasionally was extremely rapid, and abdominal distention was present for brief periods. On the eighth day examination of the spinal fluid revealed 110 cells, of which 90 per cent were mononuclear. On the tenth day the boy appeared more alert but weaker, and peripheral vascular collapse seemed imminent. The first true difficulty with swallowing appeared that night. Early the next morning he expired while sleeping quietly. Permission for necropsy was denied.

A specimen of the patient's saliva had been obtained and part of it was injected intracerebrally into mice. To another specimen of saliva penicillin was added, and the mixture was injected intracerebrally into seven other animals. The mice injected with the untreated saliva died within twenty-four hours. The mice injected with the mixture of saliva and penicillin appeared sick the next day, but on the second day 4 of them had recovered. The remaining 3 mice died of bacterial infection in from one to five days. In 1 mouse inoculated with the saliva-penicillin mixture there developed symptoms suggestive of encephalitis due to rabies on the fifteenth day. This mouse was killed, and its brain was ground in a mortar containing sodium chloride solution; the supernatant liquid was inoculated into 7 other mice, which in a few days showed symptoms of encephalitis. Negri bodies were found in the brain of some of these animals, and thus confirmed the diagnosis which had been suspected. Sections from the brain of an inoculated mouse revealed intracytoplasmic inclusion bodies in the nerve cells. Still further confirmation was provided by means of neutralization tests.

Further inquiry revealed that on the day when injury to the child's lip occurred a recently acquired puppy had acted peculiarly and had disappeared. Despite cooperation by public health agencies, newspapers, radio, police and humane organizations the pup could not be found. The dog was not known to have been in free contact with the child. The breeder from whom the pup was obtained stated that the animal had been confined closely and had not received antirabic prophylaxis; also, that symptoms of rabies were not present among its kennel mates.

The diagnosis in this case was difficult. There was no history of definite exposure to a rabid animal, and the clinical observations, physical examination and laboratory data revealed nothing specific. The changes in the cerebrospinal fluid were not in accord with those mentioned in the textbooks. Periods of hyperexcitability and hyperactivity alternating with moments of sleep or coma occur in a variety of syndromes. Fur-

thermore, the patient survived several days with little evidence of dysphagia and a complete lack of progressive deterioration.

The case here described¹ is apparently the first in which the diagnosis of rabies was established by recovery of the virus from saliva. The report suggests that the method used may be followed by others and that the saliva should first be treated with penicillin or another bacteriostatic agent before inoculation into mice, in order to minimize the chances of bacterial infection which might cause the true diagnosis to be missed.

HEREDITY IN ESSENTIAL HYPERTENSION

Weitz¹ in 1933 measured the blood pressure of brothers and sisters of hypertensive persons and found that the incidence of elevation was significantly higher among siblings of persons with hypertension than among siblings of persons without hypertension. Ayman² studied the blood pressure of every member of a family for three generations, totaling 32 members above 13 years of age. One hundred per cent of the first generation, 80 per cent of the second and 25 per cent of the third had elevated levels of the blood pressure on two or more readings. Ayman³ in a later article reported on a direct study of the blood pressure, height and weight of 1,524 members of two hundred and seventy-seven families. Elevated systolic and diastolic blood pressure readings occurred in 148 of 780 members aged from 14 to 39 years of the second generation. These 148 subjects had the same average age and sex incidence as the entire group of 780 children, but they were 14½ pounds (6.5 Kg.) above the average weight compared to 4½ pounds (2 Kg.) above the average weight for the remainder of the group. In families whose parents had absolutely normal blood pressures the incidence of elevated blood pressure in the children was only 3.1 per cent. In families in which 1 parent had arteriolar hypertension the incidence of elevated readings in the children rose to 28.3 per cent. In the families in which both parents had arteriolar hypertension the incidence of elevated readings in the children reached the striking level of 45.5 per cent. Of 70 brothers and sisters of parents whose blood pressure was normal, 37.3 per cent had elevated blood pressure readings, whereas of 86 brothers and sisters of parents with arteriolar hypertension, 65.3 per cent had elevated blood pressure readings. This unusually high incidence of elevated blood pressure readings in the children, brothers, sisters and parents of subjects with arteriolar hypertension, as compared with similar relatives of subjects with normal blood pressure, offers

1. Weitz, W.: Zur Aetiologie der genuinen oder vasculären Hypertension. *Ztschr. f. klin. Med.* **96**: 151, 1923.

2. Ayman, D.: The Hereditary Aspect of Arteriolar (Essential) Hypertension, Report of a Family, *New England J. Med.* **209**: 194 (July 27) 1933.

3. Ayman, D.: Heredity in Arteriolar (Essential) Hypertension, *Arch. Int. Med.* **53**: 792 (May) 1934.

strong evidence for the existence of a hereditary factor in essential hypertension.

Hines⁴ studied cold pressor test results in 608 persons with normal blood pressure, in ten pairs of twins and in 256 members of thirty hypertensive and non-hypertensive families. Analysis of the family history of 608 persons with normal blood pressure and of 267 persons with essential hypertension revealed that a positive family history of hypertensive cardiovascular disease was found to be five times as frequent among persons with hypertension or in those who were hyper-reactors to the cold pressor test as it was among persons who reacted normally to the test. The type of blood pressure reaction to the test in the twins and the family groups followed an inheritance pattern. Hines did not find a single hyperreactor who did not have one parent who had hypertension or was a hyper-reactor. This trait therefore appears to be an inherited dominant characteristic. The excessive or hypertensive type of reaction to the cold test occurred predominantly among members of families in which there was a hypertensive diathesis. Hines considered these observations evidence that the hereditary factor plays an important role in the development of essential hypertension. The inherited quality may be a vasomotor system which reacts excessively to certain external and internal stimuli and eventually results in essential hypertension.

Platt⁵ reported on 116 cases, 78 of which were instances of essential hypertension, 4 of probable essential hypertension, 18 of secondary hypertension, 10 of uncertain secondary etiology and 6 of doubtful origin. In 76 per cent of his cases of essential hypertension there was a family history suggestive of hypertension, and in only 6.4 per cent did the family history appear to eliminate hypertension. In the secondary hypertensive group and in the control group figures were approximately 35 and 39 per cent, respectively. These results closely correspond to those of Weitz. Platt considered that data assembled by means of history taking are not sufficient to prove that essential hypertension is conveyed as a mendelian dominant. However, the facts are compatible with the hypothesis that essential hypertension is a hereditary disease conveyed as a mendelian dominant with a rate of expression of more than 90 per cent. The importance of realization of heredity in essential hypertension has a practical aspect. In a case of hypertension of uncertain origin a strongly suggestive family history provides nearly a 6 to 1 chance that the case is one of essential hypertension, whereas if the history gives strong evidence against hypertension in the parents the chances are more than 3 to 1 in favor of some secondary cause. This is particularly important in the search for cases of hypertension with unilateral renal pathologic changes in which a cure by nephrectomy may be possible.

MORE ABOUT VAGOTOMY

The concept that the hypersecretion of gastric juices in gastroduodenal ulcer is largely neurogenic caused Dragstedt in 1943 to treat patients with intractable gastroduodenal ulceration by an operation designed to remove permanently and as completely as possible the vagus innervation of the stomach. The physiologic effect of the operation is both motor and secretory. Loss of motor function of the stomach is followed by atony and dilation. There is also a definite effect on the secretion, in most instances shown by histamine achlorhydria. The most striking effect of vagotomy on the patient with chronic peptic ulcer is the immediate and often dramatic relief of pain. The operation appears to be particularly indicated in patients who have had other surgical interventions such as pyloroplasty, posterior gastrojejunostomy or gastric resection and who have recurrent ulceration. Greatest success is noted in patients with marginal ulcer following partial gastric resection.

In a group of 170 patients on whom vagotomy was performed, Harper and Dragstedt¹ found by physiologic tests that section of the vagus nerves was probably incomplete in 18 cases. Six of these patients complained of recurrent or persistent symptoms of ulcer, and in 2 cases an undamaged vagus fiber was found at the second operation. Division of this nerve was followed by complete relief. The remaining 164 patients were free from all types of ulcer distress on an entirely unrestricted diet and without medicaments. Delayed gastric emptying and diarrhea have proved to be transitory and inconsequential. The transthoracic approach was employed in 61 patients and the transabdominal in 109. Vagotomy was combined with gastroenterostomy in 71 patients. Dragstedt considers that vagotomy is preferable to partial gastric resection when the ulcer is situated on the lesser curvature close to the esophagus, a condition which would involve nothing short of total gastrectomy. Patients in whom gastric acidity following the operation was unchanged experienced the same relief of pain. Dragstedt believes that the healing of gastric ulcers after vagotomy, although there may be only a slight change in the concentration of acid in the gastric content, suggests that other factors than peptic digestion alone may play a role in the formation of these ulcers.

In a series of 74 patients operated on at the Massachusetts General Hospital, 87 per cent of the patients, according to Moore,² have had good results and are well satisfied with their operation two to thirty months postoperatively. Five patients have had a frankly poor result either with a demonstrable recurrence or with

symptoms of ulcer. Five other patients have had sufficiently severe side effects consisting of diarrhea or other gastrointestinal manifestations to materially detract from their result. Only two postoperative gastroenterostomies have been necessary.

Grimson and his associates³ at the Duke University School of Medicine have summarized their experience on 36 patients on whom vagotomy was performed by stating that 9 of the 32 patients with duodenal ulcer are completely satisfied with the results of the operation, 22 are almost completely satisfied and 5 are only partially satisfied. They have concluded that a transthoracic vagotomy alone should not be used as a standard treatment of duodenal or gastric ulcer. They believe, however, that vagotomy may be of value when combined with gastroenterostomy or when employed for marginal ulcer.

While admitting that vagotomy will decrease or abolish gastric acidity and decrease hypersecretion and hypermotility, Lahey⁴ has objected to its routine employment because of the frequency with which gastroenterostomy is required as a part of the procedure. There is no adequate proof in his opinion that gastric acidity may not return and therefore that there may not be a continuation of the recurrence of gastrojejunal ulcers and gastrojejunal colic fistulas as a result of these gastroenterostomies. In Lahey's opinion vagotomy is the ideal procedure for a patient who has had a subtotal gastrectomy and then a recurrent jejunal ulcer.

The clinical results in 41 patients subjected to vagotomy, either alone or combined with another operative procedure and followed for from two to twenty-four months, have been satisfactory in 34 cases and unsatisfactory in 7, according to Johns and Grose.⁵ In the satisfactory group the disappearance of ulcer pain has been most striking and has overshadowed the unpleasant side effects of vagotomy, such as an increase in the number of stools with occasional diarrhea, postprandial fullness and occasional postoperative vomiting. In the unsatisfactory group 2 patients have come to reoperation, 1 for recurrence of ulceration and 1 for intractable gastric retention and dilatation caused by motor paralysis due to vagotomy. All the failures were in patients who had vagotomy without any additional operative procedure. The results have been uniformly satisfactory in the 24 patients undergoing some such procedure in addition to vagotomy.

An adverse criticism of vagotomy has been expressed by Walters and his associates⁶ at the Mayo Clinic

they summarize their experience with gastric "neurectomy" by stating that the results were inconstant, variable and in most cases unpredictable. While there was relief of pain, the patients suffered much discomfort due to dilation of the stomach, leading to retention of gastric contents. Relief of pain did not necessarily signify healing of the ulcer, since acute perforation of duodenal ulcer occurred in 1 of their cases. Reduction of gastric acidity has occurred in most instances but not in all. Some of the patients complained of frequent belching of foul-smelling gas and fullness and bloating after meals, and a few have complained of nausea and diarrhea. Subsequent operations have been necessary in some instances to remove the persistent ulcer or to provide drainage. The greatest field of usefulness for the operation seems to be in the treatment of ulcers after partial gastrectomy and in certain cases of nonobstructive duodenal ulcer in which the cephalic phase of gastric resection is definite and the pain intractable.

The period of observation is still too short⁷ to permit a final evaluation of the method. The questions of ultimate regeneration of the divided vagi and the results of the undesirable side effects of the operation, such as greatly impaired motility and dilatation of the stomach are yet to be solved.

Current Comment

A COLLEGE PRESIDENT PLACES ENGLISH FIRST

Frequently attempts have been made to stimulate interest in exposition in the minds of medical scientists. Laurence M. Gould, an eminent geologist, has noticed deficiencies in expression in the printed matter of several fields of science. By virtue of his presidency of a liberal arts college, he is in a position to urge corrective measures at the educational grade where they will do the most good. He wrote:¹

Language, which here means the English language, must therefore be the chief concern of a liberal education. Indeed the basic characteristic of an educated man is that he be "literate and articulate in verbal discourse." Here is one of the keys to the major needs of education at all levels and in all departments. . . . If I could impose my will completely at any one point . . . I would require four years of English of all students and some extra courses in composition in the senior year for those who think they want to be scientists.

If Dr. Gould is successful in thus imposing his will, and if some of his students will choose medicine as the science they wish to pursue, good will be accomplished. Their ability in medical school to conform to good English usage would not militate too strongly against them; at least some of their professors could understand them.

ORGANIZATION SECTION

Proceedings of the Cleveland Interim Session

MINUTES OF THE INTERIM SESSION OF THE HOUSE OF DELEGATES OF THE
AMERICAN MEDICAL ASSOCIATION, HELD IN CLEVELAND, JANUARY 5-6, 1948

(Concluded from Page 191)

HOUSE OF DELEGATES

Second Meeting—Tuesday Morning, January 6

Report of Reference Committee on Credentials

Dr. G. Henry Mundt, Chairman, announced that 165 delegates had been registered and that two were in process of being registered; the Speaker stated that a quorum was present and that the House was ready to proceed with business.

Roll Call

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otolaryngology and Rhinology, and carried, the House dispensed with the roll call.

Report of Reference Committee on Amendments to the Constitution and By-Laws

Dr. W. A. Coventry, Chairman, presented the following report:

1. *Section on Diseases of the Chest.*—Your Reference Committee presents the following resolution: *Resolved*, That the action of the House of Delegates in June 1947 regarding the creation of a Section on Diseases of the Chest be approved, as it conforms to the Constitution of the American Medical Association as expressed in Article 9, Section 3, page 5. Your committee recognizes that Chapter IX, Section 3, page 24 of the By-Laws allows a possible conflict of interpretation and suggests that this conflict between the Constitution and the By-Laws be referred to the Committee to Study Revision of the Constitution and By-Laws.

2. *Resolution on Increasing Annual Fellowship Dues.*—Your Reference Committee recommends that the Resolution on Increasing Annual Fellowship Dues, presented by the Board of Trustees, be adopted as amended, as follows:

Resolved, That the annual Fellowship dues and the subscription price of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION shall be fixed by the Board of Trustees and the same shall be payable in advance on the first day of January in each year provided that the annual dues shall not exceed \$12, and provided that the amount of the same shall be announced in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION not later than November 1 of each year, except that for the year 1948 such dues and subscription price of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION shall be \$12 and shall be payable in advance not later than April 1 of that year, provided that a notice of the said dues and subscription price of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION set by the adoption of this amendment is given each Fellow prior to April 1, either in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION or by mail as circumstances may indicate.

Respectfully submitted,

W. A. COVENTRY, Chairman.
HOYT B. WOOLLEY.
F. J. L. BLASINGAME.
JOHN J. MASTERSON.
J. D. HAMER.

Dr. Coventry moved adoption of the first section of the report of the Reference Committee, requesting that the matter be referred to the Committee to Study Revision of the Constitution and By-Laws. The motion was seconded by Dr. Burt R. Shurly, Section on Laryngology, Otolaryngology and Rhinology, and carried, after discussion by Dr. Arthur J. Bedell, Section on Ophthalmology; Dr. William D. Stovall, Wisconsin; Dr. F. F. Borzell, Vice Speaker; Dr. E. Vincent Askey, California; the Speaker, and Dr. Coventry.

It was moved by Dr. Coventry, seconded by Dr. Walter E. Vest, West Virginia, and carried after discussion by Dr. Thomas M. D'Angelo, New York; Dr. T. K. Gruber, Michigan; Dr. George F. Lull, Secretary; Dr. E. L. Henderson, Chairman, Board of Trustees; Dr. William Bates, Pennsylvania; Dr. Coventry, and the Speaker, who announced that a vote on this question is a change in the By-Laws, that the report of the Reference Committee on the Resolution on Increasing Annual Fellowship Dues be adopted.

On motion of Dr. Coventry, seconded by Dr. Walter E. Vest, West Virginia, and carried, the report of the reference committee was adopted as a whole.

Report of Reference Committee on Legislation and Public Relations

Dr. William Bates, Chairman, presented the following report, which as presented contains the amendments made by the House, and which was adopted section by section and as a whole after amendment, on motions of Dr. Bates, duly seconded and carried.

1. *World Medical Association.*—Your Reference Committee has considered the report rendered by Dr. E. L. Henderson, Chairman of the Board of Trustees, concerning the World Medical Association.

Your committee approves this report and recommends that the delegates and alternate delegates to the meeting of the World Medical Association be commended for the work which they have accomplished.

2. *Resolutions on Disapproval of Principles of Grants-in-Aid to All States Regardless of Established Actual Need.*—Your Reference Committee has seriously considered the resolutions from the Medical Society of New Jersey presented by Dr. T. K. Lewis with reference to Title VII of Senate Bill 545 now pending in the 80th Congress. Your committee concurs in the sense of these resolutions and is cognizant of the principle of "demonstration of need" adopted by this House of Delegates on June 13, 1944. However, your committee feels that adoption of these resolutions at this time would be politically inexpedient and might alienate valuable congressional support of our organization. Your committee recommends that this motion be not acted on at this time.

3. *Resolution on Propaganda Distributed to the Armed Forces.*—Your Reference Committee has considered the resolution presented by Dr. Herbert H. Bauckus, New York, concerning propaganda distributed to the Armed Forces. Your

committee concurs in the spirit of this resolution but recommends that the last half of the final paragraph be amended to read: "That the Board of Trustees be empowered to take any action it sees fit, after study of this pamphlet, 'Is Your Health the Nation's Business,' to call the attention of Congress again to this additional misuse of federal funds for propaganda purposes."

Respectfully submitted,

WILLIAM BATES, Chairman.
CLAUDE R. KEYPORT.
ALLEN H. BUNCE.
KARL S. J. HOHLEN.
D. A. RHINEHART.

Reference Committee on Medical Education

Dr. Creighton Barker, Chairman, presented the following report, which on motions of Dr. Barker, duly seconded and carried, was adopted section by section and as a whole after discussion, a motion to amend the third section of the report, which was proposed by Dr. B. R. Kirklin, Section on Radiology, seconded by Dr. Herbert P. Ramsey, District of Columbia, being lost:

1. *Interim Report of Committee on Nursing Problems.*—In the Interim Report of the Committee on Nursing Problems presented to the House yesterday, the Chairman, Dr. Thomas Murdock, recommended that the American Medical Association cooperate with the American Hospital Association and the American Nurses Association in the creation of a permanent conference committee to consist of fifteen members, five to be named by the Board of Trustees of the American Medical Association. The purpose of this committee is to make a continuing study of the problems related to nursing that are common to all.

The Reference Committee on Medical Education wishes to recommend the adoption of the proposal as made by the special Committee on Nursing Problems.

2. *Resolution on Endorsement of National Multiple Sclerosis Society.*—The resolution presented by Dr. Hans H. Reese, Section on Nervous and Mental Diseases, recommending that the American Medical Association endorse officially the National Multiple Sclerosis Society and its program of education of the public in this field and of undertaking investigations leading to a solution of its problem in qualified hospitals and medical centers, was approved by the Reference Committee on Medical Education.

3. *Resolution on Intern and Resident Training and Resolutions on Distribution of Interns.*—The Reference Committee received resolutions relating to the training of interns and residents introduced by Dr. Hilton S. Read of New Jersey and Dr. Edgar P. McNamee of Ohio.

The resolution received from Dr. Read asked that a committee including two general practitioners be appointed from this House to study the potentialities of requiring, in the interest of promoting general practice, a year of rotating internship before permitting a candidate to elect specialty training and to study also the supply and technics of distribution of interns and to report to this House at the June session.

The resolutions introduced by Dr. McNamee discussed an agreement for intern placement formulated by the Association of American Medical Colleges and agreed to by the Council on Medical Education and Hospitals of the American Medical Association and the American, Protestant and Catholic hospital associations. They proposed that the House of Delegates be requested to take such action as will result in rigid adherence by all hospitals to this plan for intern placement and that the House of Delegates instruct the Council on Medical Education and Hospitals to study the problem of unequal distribution of interns and formulate a plan in cooperation with the Association of American Medical Colleges and the American, Protestant and Catholic hospital associations limiting the number of interns per hospital on the basis of bed capacity further to insure an equitable distribution of interns.

These resolutions were closely related, and the Reference Committee on Medical Education wishes to submit a consolidation of them as follows:

WHEREAS, The number of positions for intern training in approved hospitals exceeds by large numbers the available interns; and

WHEREAS, It is becoming increasingly difficult each year for approved hospitals and those hospitals desiring approval to secure interns from approved medical schools; therefore be it

Resolved, That the speaker of this House appoint a special committee on Intern Placement consisting of five members, including two general practitioners, (a) to study the supply and distribution of interns with particular emphasis on furthering interest in general practice, (b) to cooperate with the Council on Medical Education and Hospitals and other interested agencies in an effort to arrive at a method leading to a better distribution of interns, and (c) to present a report of its findings and recommendations to this House at the annual session in 1948.

Respectfully submitted,

CREIGHTON BARKER, Chairman.
A. A. WALKER.
J. MORRISON HUTCHESON.
ROBERT E. SCHLUETER.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. O. W. H. Mitchell, Chairman, submitted the following report, which was adopted on motion of Dr. Mitchell, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried:

Your Reference Committee has given serious consideration to the report of the Board of Trustees regarding the increased cost of the numerous activities of the American Medical Association. These activities, so important and essential for the health of the people and the maintenance of high standards for preventive medicine, medical care and research, must be maintained.

Your Committee therefore recommends that provisions be made as soon as possible for an increase in Fellowship dues and subscription to THE JOURNAL consistent with changes which may be made in the By-Laws.

Respectfully submitted,

O. W. H. MITCHELL, Chairman.
H. G. HAMER.
E. H. CARY.
ROBERT H. HAYES.
J. B. LUKENS.

Report of Reference Committee on Reports of Officers

Dr. Deering G. Smith, Chairman, presented the following report, which on motions of Dr. Smith, duly seconded and carried, was adopted section by section and as a whole after discussion:

ADDRESS OF SPEAKER

The Reference Committee on Reports of Officers thanks the Speaker for his brief and pertinent address and expresses its appreciation of his efforts to expedite the work of the House, as was shown in the opening meeting of this session.

It is realized that the proposed revision of the Constitution cannot be considered at this session, and therefore it seems best that the consideration of the proposed revision of the By-Laws be deferred until the next annual session at Chicago, when the Constitution and By-Laws can be considered together. It is hoped that this work will be completed at that time, and it is asked that the members of the House do all in their power to expedite it.

ADDRESS OF THE PRESIDENT

1. The Reference Committee compliments the President on his report of his first six months' stewardship. The Committee appreciates his efforts to inform the medical profession and the public of the important activities in which our Association is engaged in behalf of a higher level of health for our nation. Organized medicine should realize the demands made on his time and understand his inability to accept all the invitations that he receives.

The Committee is pleased to learn that the President's recommendation of closer affiliation of medical students with this Association has been considered and that definite plans have been drawn to consummate it. It is wished to emphasize his statement in respect to public relations that "a certain responsi-

bility devolves on each doctor and employee of the profession to interpret correctly its functions in terms of public benefit."

Dr. Austin Smith and his colleagues are to be congratulated on their excellent work in writing the Handbook, and it is recommended that the Board of Trustees consider the distribution of a copy to each member so that he may familiarize himself with what the American Medical Association is doing for him and in behalf of a higher quality of medical care for the American people.

It is pleasing to learn from Dr. Bortz that the Woman's Auxiliary is reaching the goal that it hoped to attain.

2. The President's report on National Emergency Medical Service must be seriously considered by each physician, and it should be emphasized that speed is vital in the drafting of plans. It is hoped that each state society has established a similar committee, as Dr. Bortz recommended at Atlantic City, N. J., last June, but if any state has failed to do so its delegates should see that establishment of this committee is accomplished.

In conclusion, your Committee repeats the closing sentence of Dr. Bortz's admirable address: "With teamwork and loyalty, and an optimistic attitude, the membership may look forward hopefully to 1948 as one of the big years for organized medicine and, of even greater importance, through its activities to a more healthful nation."

Respectfully submitted,

DEERING G. SMITH, Chairman.
WARREN L. ALLEE.
JOHN W. GREEN.
BENJAMIN H. MINCHEW.
CLIFFORD C. SHELBURNE

Report of Reference Committee on Rules and Order of Business

Dr. Thomas K. Lewis, Chairman, presented a report, which was adopted section by section and as a whole, after amendment, on motions of Dr. Lewis, duly seconded, and carried. The report as amended reads as follows:

REPORT OF COMMITTEE TO EXPEDITE WORK OF HOUSE OF DELEGATES

Your Reference Committee has considered carefully the report of the Committee to Expedite Work of the House of Delegates. It wishes to express appreciation of the comprehensiveness and quality of this report.

1. *Administrative Matters.*—This section of the report leaves little for discussion, since it concerns itself with administrative measures already in operation at this session. Your committee wishes to congratulate the office staff for the efficient manner in which the recommendations contained in this section have been put into effect.

2. *Standing Rules:* (a) The portion devoted to reference committees advocating the appointment or nomination of reference committees in advance of session of the House in June was approved, with the following change in the last sentence of the paragraph beginning "Reference Committees," which has been altered to read as follows: "Therefore the Committee recommends that it be a standing rule that the Speaker of the House nominate reference committees two months in advance of a session, and that the list of nominees be published one month in advance of a session."

(b) The paragraph pertaining to the method of procedure by the Reference Committee on Credentials is unchanged.

(c) The next paragraph recommends that there shall be no address by the President-Elect.

(d) The next paragraph has been altered to read as follows: "A standing rule is recommended that the Reference Committee on Executive Session shall consider all matters referred to it in executive session, and shall report to the House of Delegates only when the House is in executive session."

(e) In the paragraph pertaining to guest speakers, the last sentence has been altered to read as follows: "It is recommended that a standing rule be adopted to the effect that distinguished guests shall not be presented for addresses before the House of Delegates."

(f) The next three paragraphs have not been changed.

(g) In the next paragraph the following changes have been made: In the third line from the bottom the words "two-thirds" have been deleted and the phrase at the end of the paragraph has been modified to read as follows: "(except new business presented by the Board of Trustees or the sections, as provided for in the By-Laws)," so that this paragraph will read as follows: "The Committee recommends that a standing rule be adopted that all new business and resolutions shall be introduced at the first meeting of the House of Delegates (Monday morning). However, new business may be introduced at the Tuesday afternoon meeting (or on Wednesday, if a Wednesday meeting is held) by a majority vote of the House. On Thursday no new business shall be introduced without unanimous consent (except new business presented by the Board of Trustees or the sections, as provided for in the By-Laws)."

(h) The next paragraph advocating the establishment of two separate orders of business is unchanged. The last sentence in paragraph 3 has been altered to read as follows: "It was the opinion of the Committee that the Monday meeting of the House should recess by midafternoon to allow time for an executive session in which resolutions relating to private affairs of the Association may be introduced."

(i) There have been no changes in the last five paragraphs of the report.

(j) Proposed Order of Business: In the Monday morning program of the annual session delete the words "if any" in No. 6. In the Monday afternoon meeting the following changes have been made, so that this section will read as follows: "Introduction in executive session of resolutions dealing with private affairs of the Association. (Tuesday morning shall be left open for meetings of reference committees.)" No other changes have been made in the proposed order of business for the annual session.

(k) In the Monday morning program of the proposed Order of Business for interim sessions No. 6 has been altered to read "Address of the President"; in No. 9 (1), (2), (3) and (4) the word "Chairman" should be stricken out, and No. 9 (4) should read "Council on Medical Service."

(l) The 2:30 p. m. session has been altered to read as follows: "Time for introduction in executive session of resolutions dealing with private affairs of the Association. (Tuesday morning shall be left open for meetings of reference committees)."

(m) The last paragraph in this report, pertaining to changes in the By-Laws, does not fall in the scope of activity of this committee.

RESOLUTION ON FIXING DATE OF INTERIM SESSION

It is the expressed intent of the Board of Trustees to date this session for December. However, in view of the fact that it may at times (this year, as an example) be impossible to secure necessary accommodations in the month of December, the Board of Trustees should be given greater latitude in fixing the exact date of the interim session. Therefore your committee disapproves of this resolution.

Respectfully submitted,

THOMAS K. LEWIS, Chairman.
HARRY ARANOW.
CHARLES R. ROUNTREE.
H. RUSSELL BROWN.
MORTON D. WILLCUTTS.

Report of Reference Committee on Sections and Section Work

Dr. Walter G. Phippen, Chairman, presented the following report, which was adopted section by section and as a whole after discussion, on motions of Dr. Phippen, duly seconded, and carried:

The Reference Committee on Sections and Section Work had presented to it for consideration the report of the Council on Scientific Assembly.

That portion of the report dealing with the establishment of a Section on Diseases of the Chest was referred to the Committee to Study Revision of the Constitution and By-Laws and will not be considered.

The Reference Committee approves the action of the Council in granting a Session on Allergy and one on the History of Medicine in the Section on Miscellaneous Topics at the 1948 annual session. It refrains from commenting on the Session on Diseases of the Chest pending the report of the Committee to Study Revision of the Constitution and By-Laws.

The Reference Committee approves the action of the Council in regard to the Session on Legal Medicine and suggests that the papers by Dr. Moritz and his group be included in the Section on the General Practice of Medicine.

As no proponent appeared before this Committee relative to the report of the Council in deferring action on the application for the establishment of a Section on Physical Medicine, and as no member of the Council appeared to explain the reasons for this deferment, your Committee feels that it can neither approve nor disapprove of this action.

Your Committee understands that the Council on Scientific Assembly has already conferred with the Committee to Study Revision of the Constitution and By-Laws concerning the functions of the Scientific Assembly.

Respectfully submitted,

WALTER G. PHIPPEN, Chairman.
GROVER C. PENBERTHY.
GEORGE A. UNFUG.
VAL H. FUCHS.
CHARLES T. STONE.

Report of Reference Committee on Hygiene and Public Health

Dr. William L. Estes Jr., Chairman, presented a report which on motions of Dr. Estes, duly seconded and carried, was adopted section by section and as a whole after discussion and amendment. The amended report reads as follows:

There were two resolutions referred to this Committee.

1. *Resolution on Diagnosis of Tuberculosis.*—In the deliberations of your Committee this resolution has received careful consideration, which recognizes the fact that in the application and study of the uses of the x-ray method of detecting cases of pulmonary tuberculosis in the general population, numerous organizations have been involved, notably the United States Public Health Service, state departments of health, state tuberculosis societies and medical departments of schools.

In view of our present knowledge of the value of x-ray screening in pulmonary tuberculosis as a result of the surveys and investigations of the aforementioned organizations, the Committee offers the following substitute resolution, which broadens somewhat the scope of the original:

WHEREAS, Case finding with x-rays of the chest has produced exceptional results in the early diagnosis of pulmonary tuberculosis; and

WHEREAS, The more extensive use of this method will do much toward the elimination of the incidence of this disease; therefore be it

Resolved, That the American Medical Association recognizes the great effectiveness of this method in the screening and diagnosis of pulmonary tuberculosis and will endeavor through the appropriate council, bureau or committee of the American Medical Association to further, whenever in its judgment it is indicated, activation and support of measures designed to make as widespread as possible, particularly in schools and school personnel, the use of this highly efficacious diagnostic procedure.

2. *Resolutions on Examination of Immigrants.*—In view of the testimony presented to your Committee and the impression gained that enacting these resolutions will strengthen the position that the United States Public Health Service has taken in this matter, these resolutions are approved and their adoption recommended.

Respectfully submitted,

WILLIAM L. ESTES JR., Chairman.
ROBERTSON WARD.
JAMES P. WALL.
JAMES A. CRABTREE.
W. P. ANDERTON.

Report of Reference Committee on Miscellaneous Business

Dr. Edgar P. McNamee, Chairman, presented the following report, which, on motions of Dr. McNamee, duly seconded and carried, was adopted section by section and as a whole after discussion:

1. *Resolutions on Limitation of Tenure of Office of Delegates.*—These resolutions were thoroughly considered by your Committee. Several delegates appeared before your Committee to discuss them. It is the unanimous opinion of your Committee that it is the function of the state associations to determine the number of terms a delegate should serve. Therefore your Committee recommends that these resolutions be not approved.

2. *Resolutions on Geographic Selection of Trustees of the American Medical Association.*—These resolutions introduced by Dr. William H. Halley, Colorado, proposing to select trustees of the American Medical Association from different geographical areas, were carefully considered by your Committee. Several delegates appeared before your Committee to discuss them. After thorough consideration of the resolutions and the discussions of those who appeared before your Committee, it is the unanimous opinion of your Committee that the present method of selecting trustees is satisfactory; therefore your Committee recommends that these resolutions be not approved.

3. *Report to Board of Trustees of Special Committee Dealing with Hospitals and the Practice of Medicine.*—The report of the special committee, consisting of Drs. Louis H. Bauer, Roy W. Fouts and James R. Miller, to the Board of Trustees dealing with hospitals and the practice of medicine was thoroughly considered. This special committee has recommended:

... that the House of Delegates request the Board of Trustees to appoint a committee to study the various resolutions passed previously by the House, and that this committee be directed to arrange conferences with the hospital associations and the various specialist societies in order that a solution may be worked out which will be fair to all parties and redound to the benefit of the public. It is further recommended that the report of this committee, when prepared, be referred by the Board of Trustees to the Judicial Council for such revision of the Principles of Medical Ethics as may be indicated by the content of that report.

The opinions of those who appeared before your Committee in reference to this report were given careful consideration.

Your Committee recommends that the word "specialties" be substituted for the word "subspecialties" in the first paragraph. With this correction, your Committee unanimously approves the report and recommends its adoption. Your Committee also recommends that any action taken by this committee be reported to the House of Delegates at the 1948 annual session.

4. *Resolutions on Exploiting Professional Medical Services by Hospitals.*—The resolutions, introduced by Dr. James P. Kerby, Utah, with reference to the exploitation of professional medical service by hospitals were given long and serious consideration by members of your Committee after hearing prolonged discussion by various delegates who appeared before it.

Since many resolutions have previously been adopted by the House of Delegates pertaining to this practice, and, since the delegates now assembled have just recommended the appointment of a special committee to study and take appropriate action in regard to this matter, your Reference Committee recommends that these resolutions be given consideration by this new committee.

5. *Resolutions on Regulation of the Practice of Pathology by Registered and Approved Hospitals.*—Representatives of the pathologists introduced resolutions with regard to the practice of pathology in hospitals as a source of income for the hospital. Since these resolutions fall in the same category as others dealing with the practice of medicine by hospitals, your Committee recommends that they also be given consideration by the new committee to be appointed.

Respectfully submitted,

E. P. MCNAMEE, Chairman.
FLOYD S. WINSLOW.
HOMER L. PEARSON JR.
L. W. LARSON.
B. R. KIRKLIN.

Report of Board of Trustees

Dr. E. L. Henderson, Chairman, Board of Trustees, presented the report, which was amended to read as follows:

THE TEN POINT NATIONAL HEALTH PROGRAM OF THE AMERICAN MEDICAL ASSOCIATION

PROGRESS TOWARD ACCOMPLISHMENT OF ITS OBJECTIVES

POINT 1. NUTRITION—HOUSING—CLOTHING—RECREATION

The American Medical Association urges a minimum standard of nutrition, housing, clothing and recreation as fundamental to good health and as an objective to be achieved in any suitable health program. The responsibility for attainment of this standard should be placed as far as possible on the individual, but the application of community efforts, compatible with the maintenance of free enterprise, should be encouraged with governmental aid where needed.

Progress.—The recommendation made in Point 1 should be implemented, when necessary, by the community as a whole, including the medical profession. While the essentials with which it deals are not primarily medical, they have a definite relation to health. Physicians, as an integral part of the community, are assuming their responsibilities in promoting the attainment of the minimum standard recommended. The Association has made the following contributions in an effort to promote the objectives covered by this point:

(a) In nationwide radio programs weekly over the chains of the National Broadcasting Company, sponsored by the Association, frequent mention is made of the minimum standard suggested.

(b) Local transcriptions from which 5,000 or more local programs are now broadcast annually, and which were begun in 1943, deal frequently with these topics.

(c) Constant liaison and cooperative arrangements are maintained with organizations interested in these subjects, such as the American Association for Health, Physical Education and Recreation, the American Public Health Association and other agencies.

(d) Extensive correspondence is carried on with the general public on all these subjects, plus free distribution of a wide variety of pertinent literature. Hundreds of thousands of pamphlets are distributed and almost a hundred thousand letters from the public are answered annually.

(e) Special loan collections are available on nutrition and recreation. These collections are of aid to those who speak to the public on medical subjects.

(f) Experimentally, television health education programs have been prepared and are being tried in the Chicago area.

(g) Hundreds of lectures and presentations are given in many states each year on health and fitness, stressing nutrition and recreation.

(h) Articles on recreation and physical fitness have been published in health journals.

(i) Through representatives who appear at public hearings on pending legislations the support of the American Medical Association is given to suitable legislation designed to aid in achieving essential standards of food, housing, clothing and recreation for all the people.

POINT 2. PREVENTIVE MEDICINE—HEALTH DEPARTMENTS

The provision of preventive medical services through professionally competent health departments with sufficient staff and equipment to meet community needs is recognized as essential in a health program. The principle of federal aid through provision of funds or personnel is recognized with the understanding that local areas shall control their own agencies as has been established in the field of education. Health departments should not assume the care of the sick as a function, since administration of medical care under such auspices tends to a deterioration in the quality of the service rendered. Medical care to those unable to provide for themselves is best administered by local and private agencies with the aid of public funds when needed. This program for national health should include the administration of medical care, including hospitalization to all those who need it but are unable to pay, such medical care to be provided preferably by a physician of the patient's choice with funds provided by local agencies, with the assistance of federal funds when necessary.

Progress.—The Association has been a pioneer in many phases of health education. One of the most important actions was its endorsement in cooperation with the National Health Council in 1918 of the periodic health examination. It publishes the standard manual in this field and furnishes examination blanks. Editorially, through *THE JOURNAL* and *Hygeia*, it has promoted the principles of periodic health inventories to the profession and the public.

In conjunction with the American Public Health Association and the Association of State and Territorial Health Officers, the American Medical Association supports the principle of extending county or district health department service to every area of the United States.

The principles enumerated have been supported through radio network broadcasts, transcriptions and pamphlet publications, as well as through liaison with agencies interested in the same objectives, such as the American Public Health Association and the American School Health Association.

The subject of preventive medicine looms large in daily correspondence and in the distribution of literature, and some of the latter interprets the services of health departments in this field.

There are at least twelve loan collections dealing with preventive medicine, though it might be said that virtually every one of the fifty-five different collections relates to this subject. A loan collection also deals with public health.

Preventive medicine has been interwoven into practically all television programs. The nearest approach to health department activities was the program on the activities of the visiting nurse.

Local public health units have been promoted through health and fitness talks and articles. Representatives have participated in conferences on local health units.

A health and fitness conference was held with federal public health and education agencies in December 1946 to coordinate consultative services in this field.

The Association has promoted the creation of health councils as an effective agency for effectuating health programs. County medical societies are urged to sponsor the organization of a health council.

Joint action has been taken with labor and employer groups in the elaboration of physical examination standards, in many aspects of workmen's compensation coverage and in labor-management cooperation for improved industrial health and safety.

All the available avenues for improvement of industrial medical service have been used—medical schools, general and special medical societies, dental societies, nursing organizations, agencies dealing with industrial hygiene, toxicology and chemistry and the special technical fields of preventive medicine and public health. Reports have been periodically issued describing the objectives of industrial health, the physician's place in industry, the organization of industrial medical departments, the conduct of plant hygiene surveys and many others dealing with specific procedure for industrial physicians and nurses. The Association has assisted in the development of national policies respecting the handicapped, especially those factors which depend on medical management.

Medical relations in workmen's compensation have occupied the attention of the Association. Its range of interest includes proper relations with medical societies, with specialty organizations, with industrial commissions and compensation boards and with the casualty and liability insurance industries. Efforts are being made to contribute to the improvement of administrative standards, simplification of report forms, the establishment of uniform statistical methods, improvement of medical testimony and disability evaluation and the development of far greater correlation between compensation agencies and rehabilitation services.

The Board of Trustees has supported pending legislation for federal aid in the establishment of local health units with emphasis on the principle that medical care and treatment are not properly functions of public health units.

POINT 3. PRENATAL CARE—CHILDBIRTH

The procedures established by modern medicine for advice to the prospective mother and for adequate care in childbirth should be made available to all at a price that they can afford to pay. When local funds are lacking for the care of those unable to pay, federal aid should be supplied with the funds administered through local or state agencies.

Progress.—The Association has furthered these causes through all its press, radio and public information facilities.

An officer of the Association has served as a member of the Advisory Committee to the United States Children's Bureau for nine years.

Periodic health examinations, continuously urged by the American Medical Association, begin with infancy and childhood. This activity, as discussed under Point 2, is a significant contribution by the Association to child health.

Correspondence includes maternity subjects, and thousands of copies of several pamphlets are distributed free.

A loan collection titled *Fundamentals of Prenatal Care* is available.

The health and fitness program includes stimulation of development of courses in home and family living that emphasize education for parenthood.

The Association has cooperated with the American Academy of Pediatrics, the Kellogg Foundation, the National Foundation for Infantile Paralysis, the National Education Association, the American Heart Association and many others toward achieving this objective.

In hearings on legislation tending to improve maternal and child health, representatives of the American Medical Association have supported this principle fully.

POINT 4. INFANT WELFARE—CHILD CARE

The child should have throughout infancy proper attention, including scientific nutrition, immunization against preventable disease and other services included in infant welfare. Such services are best supplied by personal contact between the mother and the individual physician but may be provided through child care and infant welfare stations administered under local auspices with support by tax funds whenever the need can be shown.

Progress.—The Association has contributed to health education of the public on these topics through radio network broadcasts, electrical transcriptions and cooperative relationships with the United States Children's Bureau and the American Academy of Pediatrics and through speakers, through the press and through *Hygeia*.

Correspondence on this subject is voluminous, and there are twenty-seven separate pamphlets available for distribution.

Thirteen loan collections dealing with various aspects of infant and child care are available.

Experimental television programs have dealt particularly with child health. Significant ones have concerned rheumatic fever and orthopedic surgery.

Health and fitness school contacts emphasize the value of immunization as a protection during the infancy and preschool period, discourage postponement of these measures to the time when the child enters school and encourage periodic checkup at appropriate points during advancement in school.

The Association has supported demonstration programs for the detection of tuberculosis, for immunization against diphtheria and for the prevention of Fourth of July injuries. It, in cooperation with the National Safety Council, is now undertaking a campaign to reduce preventable motor accidents.

In cooperation with the American Red Cross the Association has aided in extension of information on first aid and water safety.

The Association is fully supporting establishment of periodic physical examination of school children.

POINT 5. HOSPITALS—HEALTH AND DIAGNOSTIC CENTERS

The provision of health and diagnostic centers and hospitals necessary to community needs is an essential of good medical care. Such facilities are preferably supplied by local agencies, including the community, church and trade agencies, which have been responsible for the fine development of facilities for medical care in most American communities up to this

time. Where such facilities are unavailable and cannot be supplied through local or state agencies, the federal government may aid, preferably under a plan which requires that the need be shown and that the community prove its ability to maintain such institutions once they are established (Hospital Survey and Construction Act).

Progress.—These topics have received appropriate attention in radio network broadcasts, pamphlet publications, electrical transcriptions, television and talks by traveling speakers. The Association participated in the formulation of the federal hospital survey and construction act and advocated its enactment by Congress. It has made a survey of existing health centers, and the information developed will be valuable in formulating plans for construction projects under the federal law.

It has undertaken to stimulate interest in the act on the part of state and county medical societies. Discussion at regional conferences of the various problems involved in putting this act into operation has been arranged. The Association has printed and distributed 18,000 copies of a booklet explaining the federal regulations under this act and suggesting a coordinated hospital system for extension of medical care to rural areas. In the hospital field generally, it has established standards for hospitals that offer internship and residency training to medical school graduates. The institutions meeting these standards are listed annually in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*. The Association has long been interested in the number, distribution and quality of hospital services. It has cooperated at the state level in surveys of existing hospital facilities and in developing plans for needed additional facilities.

Approximately 300 hospitals closely associated with medical schools participate in the instruction of undergraduate medical students; 764 are approved by the Association for intern training; 1,017 hold approval for residencies in specialties; 1,229 maintain accredited schools of nursing education; 191 offer acceptable affiliated courses for nursing education, and 11 conduct approved schools for medical record librarians, 161 for x-ray technicians, 294 for medical technologists, 24 for physical therapists and 18 for occupational therapists.

There are 8,539 internships available in 764 approved hospitals. Great efforts have been exerted to provide opportunities for graduate study for veteran physicians desiring further training before entering practice. The number of approved residencies and fellowships have been increased from 5,256 in 1941 to 12,003 in 1946-1947, an all time peak.

In a related field, the Association has created a committee to study all phases of the nursing situation. It plans to approach the nursing problem on the basis of the number of nurses in the United States at the present time, the number needed, the number of students in nursing schools and the number that should be enrolled. The matter of retirement funds, the economic problem, the curriculums in nursing schools, the question of increasing or lowering standards of nursing and the question of courses for bedside nursing and administrative work also will be considered. The Association has been cooperating with the various nursing agencies and holds representation on the National Nursing Council and the National Association for Practical Nurse Education. It also cooperates with the National League of Nursing Education, the American Nurses Association and other nursing groups. The Board of Trustees has established a Committee on Nursing Problems which is associated with similar committees of the American Hospital Association and the American Nursing Association.

POINT 6. VOLUNTARY PREPAYMENT PLANS FOR HOSPITAL AND MEDICAL CARE

A program for medical care within the American system of individual initiative and freedom of enterprise includes the establishment of voluntary nonprofit prepayment plans for the costs of hospitalization (such as the Blue Cross plans) and voluntary nonprofit prepayment plans for medical care (such as those developed by many state and county medical societies). The principles of such insurance contracts should be acceptable to the Council on Medical Service of the American Medical Association and to the authoritative bodies of state medical associations. The evolution of voluntary prepayment insurance against the costs of sickness admits also the utilization of private sickness insurance plans which comply with the state regulatory statutes and meet the standards of the Council on Medical Service of the American Medical Association.

Progress.—The Association has undertaken the promotion of voluntary prepayment medical care insurance. In this promotion studies have been prepared on the various types of prepayment plans sponsored by medical societies, and in order to stimulate the program there has been created the "Seal of Acceptance" and preliminary standards for granting that "Seal of Acceptance" have been formulated.

During 1947, seven plans or programs in as many states completed organization. This brings the number of states in which programs are in operation to thirty-eight. Plans are in various stages of development in the other ten states and the District of Columbia. Details of some of these proposed plans are almost complete, and some hope to begin operation on or about Jan. 1, 1948.

Enrolment in medical service plans continues to grow—over 6,503,000 as of Sept. 30, 1947—and is still increasing rapidly. The net increase for the first nine months of 1947 is approximately 2,000,000. The rate of growth approximates closely that of the Blue Cross Hospital Plans.

Many plans are now tending to provide a broader coverage, extending benefits to smaller groups or even to individuals, and are carrying the program into the rural areas.

Realizing that there were many details in the business operation of voluntary prepayment plans with which its staff was not equipped to cope, the Association has been instrumental in creating a national organization of the plans themselves. This national organization is a trade association designed to work with the internal problems of prepayment plans.

Recognizing that a single type of plan could not adequately meet the entire prepayment program, the Association has encouraged the development of adequate prepayment insurance coverage by private insurance carriers. Five state medical associations have approved this type of program, and several others are considering it at the present time. All the promotional and publicity facilities of the Association have been used in expanding this program.

The Association actively promotes the extension of medical care to rural communities through prepayment plans and otherwise. It collaborates with the various farm organizations to devise ways and means to attain this objective. It sponsors annual conferences at which leaders of farm groups of the medical profession and other leaders in the health field assemble to explore the problem of rural medical care. It has stimulated the creation of rural health committees by its state and county units.

It has conducted surveys, with the cooperation of state and county medical societies, of the medical facilities and medical personnel in every county of the United States; the information obtained was made available to all medical schools and to all hospitals approved for internships and residencies for the purpose of helping the young physician to choose his place of practice.

A survey of medical schools in 1947 disclosed that many of them have preceptorships with rural physicians for medical students in their senior year, scholarships for students who will practice in rural areas, rotating internships from university hospitals to rural hospitals, extension of medical care from medical schools to rural clinics and other similar projects.

The Association is concerned with the cost of medical care, with the distribution of physicians and with the utilization of their services. Prepayment plans organized and operated by physicians will do much toward lessening personal disaster and suffering occasioned by accident or the onset of disease.

Studies have been made of the medical care available to civilians during World War II by means of a questionnaire survey of thousands of physicians who remained home during the war—those who comprised the 60 per cent of practicing physicians who carried the 91 per cent of the prewar patient load. The results of their efforts? The year of 1942, the first year of heavy inductions, was the healthiest year in the history of the United States up to that time. The purpose of the study was to determine if even better results may be obtained in event of another national emergency.

A similar study has been made of the utilization of medical personnel by the armed forces during the war, conducted by questionnaires sent to all medical officers discharged before

Dec. 31, 1946. This study summarizes the opinions and constructive criticisms made by the nation's wartime medical officers. The results of this survey will be of great value in assisting the Department of National Defense to plan its medical policies for the future of the entire national defense establishment in peace, in preparedness and in war.

The first really definitive study of the supply of physicians in the United States is being carried out by the Association.

This study is not based on the outdated concept of numbers of physicians and persons in each county, but rather seeks to group all physicians with their patients into the naturally formed service areas that, in fact, develop about each center at which physicians' services are available. Thus for the first time will it be possible to state exactly the ratio of physicians to population for each part of the United States—and to do it without the constrictions of economically unrealistic political boundaries. It will be known for the first time where physicians are, where their patients are and how many of each are to be found in each medical service area. Each part of the United States will fall into some one of these medical service areas, and it will be on differences found to exist between these areas that true reforms in distribution of medical care will be founded.

Foreseeing a growing demand for more integration and organization in the supply of medical services, the Association is conducting a far reaching study into the implications of group medical practice. In this study it is accepted as a basic premise that organization in medical care presents problems other than those of medical care alone. The study visualizes "group medical practices" as, in part, separate business firms to be studied in the light of success or failure as business firms. For this reason, great attention is being paid to discovering the reasons for the disappearance of so many of the group medical practices which sprang up in recent years. Through learning the reasons for failure, it will be easier to provide guides for successful operations for other and for new groups.

The American Medical Association has contributed largely of its own funds in furthering the objective of widespread voluntary insurance against the costs of sickness and hospitalization.

POINT 7. VETERANS' NEEDS FOR HOSPITAL AND MEDICAL CARE

A program for national health should include the administration of medical care, including hospitalization, to all veterans, such medical care to be provided preferably by a physician of the veteran's choice, with payment by the Veterans Administration through a plan mutually agreed on between the state medical association and the Veterans Administration.

Progress.—The Association has followed closely the development of the Veterans Administration Home Town Medical Care Program. At the present time over thirty-five state medical associations are working with the Veterans Administration in providing this free choice of physicians program to the veterans. In practically all the Association's regional conferences the various participating state medical associations have been given an opportunity to discuss problems arising under the program with representatives of the Veterans Administration.

A special committee on Veterans' Affairs has been created to study problems that may arise and to confer with representatives of both the state medical associations and the Veterans Administration. A National Conference on the Veterans Administration Home Town Medical Care Program was sponsored by the Association in November 1947. Representatives of thirty-five state medical associations, the various specialty groups, the Veterans Administration and the American Medical Association participated in this conference. The Veterans Administration is concerned with the continued medical and hospital care of the men and women who served in the armed forces and is making every effort to improve the quality of medical and hospital care. To this end the Veterans Administration sought the cooperation of the faculties of the medical schools. To date sixty-five Veterans Administration hospitals are affiliated with medical schools and have been approved for the training of resident physicians by the American Medical Association. These institutions with two hundred fifty training programs provide at the present time opportunities

for the training of 2,100 resident physicians. The Association has cooperated closely with the Veterans Administration on its program of research on the effects of streptomycin in tuberculosis. Early publication of the results of the studies made by the Veterans Administration was secured, thus enabling the entire medical profession and the public to benefit immediately from the important conclusions reached by the physicians in charge of the care of tuberculous veterans.

The Council on Medical Education and Hospitals has inspected veterans' hospitals and approved internships and residencies.

The Association has aided the work of the Committee on Veterans Medical Problems of the National Research Council and has extended research in veterans' hospitals.

POINT 8. RESEARCH FOR ADVANCEMENT OF MEDICAL SCIENCE

Research for the advancement of medical science is fundamental in any national health program. The inclusion of medical research in a National Science Foundation, such as proposed in pending federal legislation, is endorsed.

Progress.—The American Medical Association sponsors research in a variety of ways; in fact, practically everything that it does encourages research or the use of knowledge gained from research. It disseminates through its scientific publications the results of such research or lists the research projects in its *Quarterly Cumulative Index Medicus*, which is the source of reference for scientists engaged in gathering material to serve as the basis of scientific projects and arguments, and which is used by readers to advance their information in the field in which they are interested.

The Association examines drugs, foods and devices and similar preparations to determine their efficacy, and when this is wanting makes suggestions for further research to show the true usefulness of the product under consideration. It maintains a laboratory to test the preparations submitted for consideration. One of the important aspects of this unit is concerned with the development of new tests and standards by which products can be identified and controlled. When new products are placed on the market, there is no control except that set forth by manufacturers. When these products are submitted to the Association, tests and standards are devised which later are usually picked up with slight modification by the United States Pharmacopoeia, which is recognized as an official compendium under the provision of the Federal Food, Drug and Cosmetic Act.

The Association has created three special committees which have medical research functions. One is designed to bring together a new idea from an individual or group of individuals and research workers who are qualified to investigate that idea. For example, a firm might produce a new treatment for tuberculosis or some one else might devise a new method of approach to the problem of poliomyelitis, arthritis or rheumatic fever. This committee will arrange for research and undertake to contact the experts in this country, to organize the program and to see that it is most expeditiously conducted with the expenditure of a minimum of time and money. This committee has participated in a collaborative Study of Steroids and Cancer initiated by it, which represents a voluntary coordinated attack on the problem of cancer with participation by the general medical profession, government agencies, pharmaceutical manufacturers and the Association. Through the efforts of the committee, medical scientists in all parts of the country are being encouraged in their research, and an attempt is being made to bring support to scientists in institutions for which such support has been inadequate or lacking. At the request of the National Foundation for Infantile Paralysis, Inc., this committee undertook to explore the feasibility of conducting certain critical investigations on the treatment of poliomyelitis and to design an experiment to test certain hypotheses. It is cooperating with the American Red Cross in its research on blood and blood derivatives.

A second committee makes available funds for research purposes (this year about \$10,000; normally around \$15,000). The grants are small, usually amounting to several hundred dollars and seldom over \$1,000 or \$2,000. They are given to persons working on therapeutic problems in medical schools and elsewhere who need help to underwrite part of their

problem. Over six hundred such grants have been given through this committee since it was organized in 1911.

A third committee also makes available funds for scientific research on a somewhat broader basis than that under which the second committee functions. During 1946, sixteen grants ranging from \$250 to \$2,600 were made. During the year, work was in progress on twenty-four projects for which grants had been made in previous years, and grants were closed on an additional ten research projects.

In 1947 the Board of Trustees established a trust fund in the amount of \$1,500,000, the interest from which will be used each year to support medical research.

The Association stimulates fundamental research and clinical investigation in industrial medicine and surgery, industrial hygiene, sanitation, medical administration and other disciplines dealing with occupational health.

The Association makes available exhibits for scientific and lay groups, for medical and other organizations—exhibits which range from the value of early diagnosis of cancer to the latest treatments for tropical diseases. The scientific exhibits at the annual and interim sessions of the American Medical Association are part of the highlights of these sessions. The exhibits that are made available on loan to state medical associations, county medical societies, women's auxiliaries, local health organizations, the Veterans Administration and other groups are extremely popular, and their popularity reflects their value.

Much research is done in medical schools, and the Association promotes that research by stimulating the schools to maintain high standards. The last comprehensive survey of medical education in this country was that conducted by the Association during the period 1934-1936. This report proved to be of great value. The Association is sponsoring a resurvey of medical education in cooperation with the Association of American Medical Colleges. The objectives of the study are: (a) improving medical education to better meet the overall needs of the American people for (1) the prevention of disease, (2) the restoration, as far as possible, to health of all those who suffer illness or injury and (3) the maintenance of the best standards of physical and mental health of all the people; (b) assessing the degree to which medical schools are meeting the needs of the country for physicians; (c) promoting the advancement of knowledge in the field of medical science, and (d) better informing the public concerning the nature, content and purposes of medical education.

An important aid to the physician who desires to keep abreast of the progress of medicine is the offering of continuation courses throughout the country. This type of training is offered in variable periods from a few days to several months. Some are concentrated full time courses and others are part time. In thirty-three states and the District of Columbia some form of continuation study* for practicing physicians was provided during 1946-1947. The total attendance numbered 59,811, which represents the greatest number to seek such opportunities in a single year. The listing of these opportunities is published semiannually by the Association. The last listing included more than eight hundred courses.

Programs have been initiated in seven states providing for state scholarships for medical students who, on completion of their training, agree to practice medicine in a rural community of the state. In Indiana, Illinois and Kentucky the rural medical scholarship fund was created by a statewide campaign sponsored by the state medical associations.

The Association has waged a constant battle against antivivisectionism, antivaccinationism and the antiscience movement in general through its radio network broadcasts, electrical transcriptions, television programs, pamphlet publications and speakers.

It has frequently analyzed and refuted the claims of antivivisectionists and is actively cooperating with the National Society for Medical Research, and it has always cooperated with medical schools and other research agencies in defense of the use of animals for medical research under appropriate regulations, which insure humane treatment of laboratory animals.

Through health education, the Association has endeavored to establish and promote scientific thinking on the part of

the public as a broad base for appreciation of medical science and its progress through medical research.

This interpretation has likewise been carried out through radio network broadcasts, electrical transcriptions, pamphlet publications, Question and Answer correspondence and traveling speakers.

Loan collections in which advancement of medical science is emphasized include those on alcohol and tobacco, anesthesia, deafness and hearing aids, heredity and eugenics, narcotics, superstitions, outstanding medical advances and progress in preventive medicine.

Representatives of the Association participate in the activities of many foundations, health organizations and similar groups which extend medical research.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION promotes research in articles and editorials and aids in developing funds for research.

POINT 9. VOLUNTEER HEALTH AGENCIES— PHILANTHROPIC FUNDS

The services rendered by voluntary philanthropic health agencies such as the American Cancer Society, the National Tuberculosis Association, the National Foundation for Infantile Paralysis, Inc., and by philanthropic agencies such as the Commonwealth Fund, the Rockefeller Foundation and similar bodies have been of vast benefit to the American people; and are a natural outgrowth of the system of free enterprise and the democracy that prevail in the United States. Their participation in a national health program should be encouraged, and the growth of such agencies when properly administered should be commended.

Progress.—The Association has always cooperated with the voluntary agencies. When the National Tuberculosis Association, now the most powerful and heavily financed of these organizations, was in its infancy, its publications were issued jointly with the American Medical Association and were printed by the American Medical Association. Leading members of the Association have played leading parts in the organization and development of voluntary agencies.

The Association, with the National Education Association, organized the Joint Committee on Health Problems in Education, which constituted a pioneer in health education. This committee publishes the standard textbook in that field, entitled "Health Education," and numerous other pamphlet publications, as well as contributions such as symposiums at the annual meetings of the National Education Association, Association of School Administrators, the Association for Health, Physical Education and Recreation and the American Medical Association's own meetings.

Personnel of the Association now are, or have been, consultants to, or members of, advisory committees for the following organizations:

- The President's Highway Safety Conference
- The American Red Cross Advisory Committee
- The American Red Cross Home Safety Commission
- 1942 Yearbook Commission—American Association of School Administrators
- United States Children's Bureau
- United States Public Health Service
- Office of Price Administration Committee on Health Aspects of Fuel Rationing
- American Public Health Association
 - Governing Council
 - Subcommittee on Accident Prevention
 - Committee on Professional Education
 - Secretary and Chairman of Health Education Section
 - Consultant on Merit System Unit
 - School Health Section
 - Public Health Film Committee
- American Cancer Society—Health Education Committee
- Chicago Council on Social Service Agencies—Health Committee
- National Organization for Public Health Nursing—Consultant
- National Safety Council
- The American Camping Association—Consultant
- United States Indian Service—Consultant
- United States Department of Commerce
 - Accident Prevention Conference
- National Congress of Parents and Teachers
 - Committee on Health and Summer Round-up
- National Committee on Boys' and Girls' Club Work (4-H)
- American School Health Association, Governing Council
- American Association of Teachers Colleges, Committee on Standards and Surveys
- Joint Committee on Planning for the Chronically Ill
- National Research Council, Subcommittee on Tuberculosis
- American Student Health Association, Governing Council
- Illinois State School Health Committee on Personal Hygiene

- American Association for Health, Physical Education and Recreation
- Committee on Standards for Interscholastic Athletics
- National Conference for Cooperation in School Health Education
- American Film Center, Committee on Public Health
- National Health Council, Committee for Study of Voluntary Health Agencies
- General Federation of Women's Clubs
- American Heart Association
- American Conference on Rheumatic Fever
- National Foundation for Infantile Paralysis

The Association has worked with representatives of the American Hospital Association, the American Public Welfare Association and the American Public Health Association in developing a program for the chronically ill. Realizing that the problems of the chronically ill will undoubtedly increase as the average age of the population increases, these three associations, together with the American Medical Association, are attempting to evaluate the situation and to lay plans for its solution.

Representatives of the American Medical Association have served on advisory boards of the medical departments of the Army, the Navy, the Federal Security Agency, the United States Public Health Service, the National Foundation for Infantile Paralysis, the Children's Bureau, all the various educational associations, all the associations of technical specialties allied to medicine and the American National Red Cross, as well as local and state agencies. The publication facilities and expert personnel of the Association have been lent freely and for considerable periods of time to practically every important agency in any way related to health.

Recent activities include committees to cooperate with the National Tuberculosis Association, the American Public Health Association and the United States Public Health Service in establishing minimum standards for the detection and prevention of tuberculosis and for educating the public on this subject. The Association has endorsed international conferences on tropical disease, infantile paralysis and children's diseases, and in many other ways has extended the influences of American medicine throughout the world. Most recent activities are cooperation in establishing the World Medical Association with representation by the American Medical Association at the organization of this body in Paris, France, and with the establishment of the headquarters office of the World Medical Association in New York. A United States Committee of the World Medical Association has been established to extend the accomplishments of American medicine throughout the world.

POINT 10. HEALTH EDUCATION IN PREVENTION OF DISEASE

Fundamental to the promotion of the public health and the alleviation of illness are widespread education in the field of health and the widest possible dissemination of information regarding the prevention of disease and its treatment by authoritative agencies. Health education should be considered a necessary function of all departments of public health, medical associations and school authorities.

Progress.—The Association has not been a laggard in the field of health education but has been a pioneer. It has continuously expanded and augmented its program of health education through the following principal mediums:

- Hygeia, the Health Magazine*, established in 1923
- Radio broadcasting begun in 1925
- Electrical transcriptions started in 1943
- Health and Fitness programs started in 1946
- Television programs started in 1946

The Association, together with the National Health Council, endorsed the principle of periodic health examinations and, with the exception of commercial insurance companies, has been the only national organization to continue active sponsorship and promotion of that concept.

As this is a basic activity, it is represented in every phase of question and answer service, loan collections and television programs. Special material intended for teacher-pupil use is included among the literature available.

Health and Fitness activities in this connection have included:

Sponsoring of Conference on the Cooperation of the Physician in the School Health and Physical Education Program, October 1947, including representatives of health departments, education departments, medical societies and education associations from thirty states and one territory and representing ninety agencies.

Providing consultation services at working conferences in Arizona, Florida, Illinois, Louisiana, Minnesota, Missouri, New Jersey, Texas, Utah, Virginia and Wisconsin.

Providing consultation services at National Conference on Health in Colleges, May 1947, and at national meeting of American Association for Health, Physical Education and Recreation, April 1947.

Editing of Recommendations for the Health Appraisal of School Children and assisting in preparation of report "Health Education" for Joint Committee on Health Problems in Education.

Service on twelve national committees related to health and health education such as the Committee on Standards and Surveys of American Association of Teachers Colleges, School Health Section Council of the American Public Health Association, Committee on Standards for High School Athletics.

Publication of articles on health and fitness in ten periodicals such as *National Parent-Teachers*, *Hygeia* and the *Journal of Health and Physical Education*.

Answering of 2,500 letters a year on school health problems from teachers, physicians and school officials.

The Association issues each week to some 2,000 periodicals and newspapers a release from the publications of the American Medical Association to inform the public on the progress of medicine.

Members of the headquarters staff contribute to innumerable public periodicals, and the headquarters office constantly reads and considers articles for the education of the public in health prepared by other agencies. Representatives of the Association advise other agencies in the techniques of education of the public in health and in the prevention of disease, many of which techniques were first developed in the headquarters of the Association.

Exhibits prepared by the American Medical Association are developed and lent to many other agencies. The association has prepared some motion pictures and cooperates with many other agencies in the preparation and dissemination of most pictures related to the prevention of disease.

Hundreds of addresses are given annually by members of the official bodies and staff of the American Medical Association to clubs and societies and other groups.

The Woman's Auxiliary to the Association participates in health activities of innumerable women's clubs and parent-teacher associations and similar agencies and extends widely the work of health education.

The Association has urged (1) extension of education on health to schools in every grade and (2) recognition of health education as a subject to be assigned credit for accomplishment as with other major subjects. Literally millions of books and pamphlets prepared by the American Medical Association to aid the public in health education have been distributed. *Hygeia* is the most widely quoted health magazine in the world, and its material has been extended most widely not only to all digest magazines, newspapers, radio stations and similar agencies in the United States but to Canada, South Africa and Australia and to foreign language publications in Chinese, Hindustani, French, German, Spanish, Italian and the Scandinavian languages.

In approving the foregoing account of progress made by the American Medical Association in achieving the objectives of its Ten Point National Health Program, the Board of Trustees recommends the following additional activities:

In order to bring the best possible medical care to the American people the Association must:

1. Increase public health and preventive medicine facilities so that the whole country is covered, thereby reducing the incidence of illness and the need for medical care. This will require joint health departments for poorly populated counties and will in some instances require federal grants-in-aid.

2. Provisions for prenatal care, childbirth, infant welfare and child care must be expanded in some areas, again with federal grants-in-aid to assist in the cost, the administration to be on a local basis.

3. Hospitals and diagnostic facilities must be expanded along the lines provided in the Hill-Burton bill, so that all will have these facilities. This will make it possible to give better care and will attract physicians to areas now lacking them. It should be borne in mind that mere appropriation of money is not sufficient. The money available under the Hill-Burton Act is not being fully used because of a lack of materials and labor. Further, the doctors, nurses and technicians must be available to make these units function.

4. Before considering insurance, it must be remembered that as far as medical care is concerned there are four economic groups to consider: (a) those who are sufficiently well off financially to care for themselves under any conditions, no matter how prolonged or costly the illness; (b) those who are sufficiently well off financially to care for themselves under all conditions except prolonged or costly illness; (c) those who can care for themselves under ordinary circumstances, but who find it difficult to meet the cost of any illness, and (d) those who are wholly dependent on the public welfare for even their housing, clothing and food.

Economic group *a* does not require action.

Group *d* is well cared for on a charity basis in most areas, but certain better arrangements must be made in a few areas. The problem here is a social one of raising the economic level of the group rather than a medical one.

It is group *b* that voluntary insurance will cover satisfactorily as to both hospitalization and medical care. Both types of insurance are expanding rapidly, and there is no reason to believe that they will not meet the needs of this group. While this insurance is available largely on a group basis, it apparently is not clearly understood that one can form groups in different ways. For example, a person may form a group among his neighbors.

It is group *c* for which further provision is needed.

One way of solving this problem would be that outlined in Senate Bill 545. The American Medical Association has not endorsed this bill in toto but has approved it in principle. The bill provides that the federal government shall allot funds to states for expenditures under their regulations, subject to federal control only as to the general plan.

This bill provides that this money will be available if a state sets forth a statewide program designed and calculated to provide within five years: (a) hospital services, surgical services and medical services for all those families and individuals in the state having insufficient income to pay the whole cost of such; and (b) periodic physical examinations for all children in elementary and secondary schools in the state.

Such program may, at the option of the state, provide medical care services in one or more of the following ways: In institutions, in the home or in physicians' offices. This program may also provide for the furnishing of these services to such families and individuals by means of payments (in the nature of premiums or partial premiums or reimbursement of expenses or otherwise) by the state to any voluntary health, medical or hospital insurance fund, or other fund operated not for profit, in behalf of those families and individuals unable to pay the whole cost of such services or insurance therefor. Such program shall provide for the collection of proper charges of less than the total cost of such services from persons who are unable to pay in whole but who are able to pay in part therefor. Such program may include and take account of services rendered or to be rendered by governmental subdivisions of the state and by private organizations operating not for profit, and may provide for the payment to such institutions by the state or subdivision for care to such families and individuals. Such program may also include payments to physicians practicing in areas which, without such payments, would be unable to provide sufficient income to attract a practicing physician.

The total amount necessary for this purpose is not known. S 545 provides for an appropriation of \$200,000,000 a year. This may be sufficient but probably will not be. The exact amount will have to be determined finally after experimentation. In setting the level for assistance, local areas must make the decision.

Furthermore, any program must start slowly and develop slowly, so that the facilities necessary—such as doctors, nurses, technicians and hospitals—will be trained or established to keep pace with the demands of the program. The problem cannot be solved by the stroke of a pen.

Finally, any program, no matter how perfect, will become ineffective with increasing inflation.

PUBLIC RELATIONS PROGRAM

Knowing the interest of this House of Delegates in the public relations program of the American Medical Association at this time the Board of Trustees wishes to tell the House that it has employed a consultant and an executive assistant to Dr. Lull in charge of public relations and also to introduce these gentlemen to the House.

INTRODUCTION OF MR. THEODORE R. SILLS

Mr. Theodore R. Sills is head of Theodore R. Sills and Company, public relations firm, which has been retained by the American Medical Association as counsel. His offices are in Chicago and New York. Mr. Sills is coauthor of the book "Public Relations—Principles and Procedures." He was formerly president of the Chicago Chapter of the National Association of Public Relations Counsel and is now vice president of the national organization. He handled public relations for the steel companies in the Little Steel case that led to the Little Steel Formula. He has directed public relations for the American Dental Association, the American College of Radiology and

many large corporations such as Inland Steel Company, Brunswick-Balke-Collender Company, Sunshine Biscuits, Inc., and for refrigeration, air-conditioning and radio manufacturers, the American Bakers Association and others.

ADDRESS OF MR. THEODORE R. SILLS

Thank you very much, Dr. Henderson. We are very happy to be associated with the American Medical Association, and we are looking forward to working with you and your public relations director, Mr. Lawrence W. Rember, in helping solve your public relations problems successfully.

INTRODUCTION OF MR. LAWRENCE W. REMBER

Dr. E. L. Henderson, Chairman, Board of Trustees, introduced Mr. Lawrence W. Rember as the newly appointed executive assistant to Dr. Lull in charge of public relations, a man who brings considerable experience, education and training to his position in the American Medical Association.

Mr. Rember directed public relations nationally for the Blue Cross plan of the United States and Canada. He served as public relations director for seventeen states for the American National Red Cross.

Recently he was assistant general manager of the Public Relations Nutrition Agents, representing twenty-eight national and regional trade associations in the food field.

He served five years with a newspaper and two years with a national advertising agency. He was graduated with honors at the University of Wisconsin with a bachelor of arts degree, and at Northwestern University with a master's degree in science.

Mr. Rember supplemented this education in arts and sciences and professional journalism, advertising and public relations by teaching at the Henry W. Grady School of Journalism at the University of Georgia. He is director of the Chicago Chapter of the National Association of Public Relations Counsel. The Board takes pleasure in presenting Mr. Rember.

ADDRESS OF MR. LAWRENCE W. REMBER

Mr. Speaker and Members of the House:

It is a privilege and a challenge to me to be associated with the American Medical Association. I say this because I believe genuinely that the American doctor, American medicine and the American voluntary way will solve economic and social problems.

I assure you that when we can be of any service to you and your societies at national headquarters, we want you to call on us.

INTRODUCTION AND ADDRESS OF MR. JOHN BACH

Dr. E. L. Henderson, Chairman, Board of Trustees, reported that Mr. John Bach, who has been with the American Medical Association for several years, has been doing some excellent work in public relations. Mr. Bach, will you stand? Most of you know Mr. Bach. He has been with us in the press room at our sessions for a number of years.

Mr. John Bach spoke as follows: Gentlemen: It has certainly been a pleasure working for the last several years in building up the press relations of the American Medical Association. We still have a way to go. If we have the cooperation of all you doctors, we will certainly do the best we possibly can.

Dr. Henderson reported further that the Board of Trustees realizes that a great number of the delegates have felt that it has been dilatory in public relations. The Board has spent a great deal of time investigating various organizations and various men endeavoring to get the proper set-up for the public relations of the American Medical Association, and the Board believes and hopes that this has now been accomplished.

Presentation and Address of Dr. T. C. Routley

The Speaker introduced Dr. T. C. Routley, secretary of the Canadian Medical Association, who addressed the House as follows:

Mr. Speaker, Mr. President, Ladies and Gentlemen:

I see that you are just as human as people are elsewhere. The first thing you do is pass a rule, and then you break it.

I must confess, however, Mr. Speaker, that I feel distinctly honored in this unique opportunity which has been given to me to be the first one to break that rule.

I would be guilty indeed of transgression if I spoke to you at any length, but I cannot resist the temptation while here of saying one or two things to you.

You have heard from your officers of your participation in the work of the World Medical Association.

Mr. Speaker, I should like to underline the words I am now about to use. One hundred and twenty-five delegates from forty-eight nations met in Paris in the month of September. This great body was represented by four delegates: Drs. Henderson, Bauer, Irons and Sensenich. They will forgive me, I am sure, if I say that they proved to be four outstanding medical statement.

There were occasions in Paris, trying moments, when patience, tolerance, long suffering and vision were required. These men exemplified those qualities in a high degree, and it was largely because of these men that we came away from Paris with the structure of a World Medical Association which some of us believe may mean much to the future welfare of this world.

I think all mankind craves two things: Opportunity, and ability to discharge the obligations which that opportunity presents. Ladies and gentlemen, world medicine today gives that opportunity, and this great American Medical Association is going to demonstrate to the rest of the world what is meant by the American way of life. You are going to prove to the rest of the world that man can give without immediately looking for a quid pro quo.

You are going to show the outer ramparts of the world that you come bearing gifts, gifts which are calculated to assist all mankind to attain the highest possible level of health.

Incidentally, you are going to do much to promote world peace. This is the day of the atomic bomb versus man's humanity to man. We in medicine surely stand, as the ministry of healing, for that great thing in life of helping mankind to live, not to die.

I am thrilled, Mr. Chairman, to be associated with such a group of people. We are opening our office of the World Medical Association in the city of New York in March of this year.

We are not at the moment in a position to tell you the name of our full time executive secretary, but I can assure you that when that name is announced it will come with great pride and pleasure to this body.

In a final word, Mr. Chairman, which I should have said at the outset, I bring you greetings from your brethren in medicine in Canada, and I say to you that your way of life and our way of life marching along together perhaps will demonstrate to the world what we mean when we say we should like mankind to endure in peace and harmony.

Introduction of Four Canadian Physicians

Dr. T. C. Routley, Secretary, Canadian Medical Association, introduced four Canadian physicians who stood up to be recognized as their names were called: Dr. A. D. Kelly, assistant to Dr. Routley; Dr. H. S. Dunham, secretary of the Interior Division; Dr. C. C. White, president of the Ontario division of the Canadian Medical Association, and Dr. Victor Johnson, a general practitioner from Lucknow, Ontario, Canada.

Motion to Recess

It was moved by Dr. Thomas K. Lewis, New Jersey, seconded by Dr. Thomas M. D'Angelo, New York, and carried, after discussion, that the House recess until 2:30 p. m., at which time it would go into executive session.

Tribute to Dr. C. W. Roberts and Dr. Holman Taylor

Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, requested the Speaker to ask the members of the House to stand for a minute in tribute to the memory of Drs. C. W. Roberts and Holman Taylor, deceased. The Speaker so requested the House, whose members stood in silent tribute for one minute.

Resolutions on Exposing Activities of Certain Employees of the Federal Government in Efforts to Socialize Medicine

Dr. Clark Bailey, Kentucky, presented by title resolutions complimenting the Subcommittee of the Congress of the United States in exposing activities of certain employees of the United States government in their efforts to socialize medicine. The resolutions were referred to the Reference Committee on Executive Session.

The House recessed at 12:30 p. m. to reconvene at 2:30 p. m.

Executive Session

The House of Delegates met in Executive Session in the Euclid Ballroom of the Hotel Statler, Cleveland, being called to order at 2:45 p. m. by the Speaker, Dr. R. W. Fouts.

The Speaker announced that at the Atlantic City Session in June 1947 there had been adopted the report of the Reference Committee on Reports of Officers, reading "your reference committee makes the recommendation that only members of the House of Delegates as defined in article 5, section 2, and the general officers as defined in article 6, section 1, of the present Constitution and By-Laws shall be present at an executive session. The House, by a two-thirds majority, may, however, invite to be present any individual who in its judgment might assist in the deliberations." He then read to the House article 5, section 2, and article 6, section 1, of the Constitution concerning the composition of the House of Delegates and the general officers of the Association.

The Sergeant at Arms reported that it was his belief that all those in the House were entitled to remain.

Report of Reference Committee on Medical Service

Dr. E. S. Hamilton, Chairman, presented a portion of the report, with the statement that it also had the approval of the Reference Committee on Executive Session, the members of which had examined it and suggested that it be submitted in Executive Session. This section of the report of the Reference Committee, as follows, was adopted on motion of Dr. Hamilton, seconded by Dr. Thomas A. Foster, Maine, and carried after discussion:

PROGRESS REPORT OF COUNCIL ON MEDICAL SERVICE

Your Reference Committee has reviewed the progress report of the Council on Medical Service for the Interim Session of the House of Delegates and wishes to commend the Council for its continued activities and progress in this regard. It wishes particularly to comment on two portions of the report:

1. *Washington News Letter*.—It is the opinion of the Reference Committee that this should be presented in a more interesting and attractive form. In all probability at present it is not reaching the physicians who need it the most, and if its distribution could be increased to include local physicians, the Committee thinks that it would be of greater value.

2. *Prepayment Medical Care Plans*.—Your Reference Committee read with great interest the report of the extension of voluntary prepayment medical care plans and wishes to commend the Council for its activities in this regard.

It is the opinion of your Reference Committee that certain conditions have arisen within the last few months which are of vital importance in the continuation of the voluntary prepayment medical care plans, and it feels that it would be well for the Council on Medical Service to render to the House of Delegates a concise report of what has occurred and what effect, if any, these developments will have on the future work of the Council on Medical Service. Your Committee would like the following information: (1) the position of the Council relative to approving plans other than those sponsored by nonprofit groups; (2) recent rumors of proposed developments relative to the affiliation of the Blue Cross and the Associated Medical Care Plans under the direction of Dr. Hawley, and (3) plans for future

activities of the Council in regard to the furtherance of voluntary prepayment medical care plans of all kinds.

At this time your Reference Committee thinks it proper to recommend that the House of Delegates reinstruct the Council on Medical Service to continue to correlate and extend voluntary prepayment medical care plans in all phases as rapidly as possible throughout the United States to cover as large a percentage of the population as possible, particularly the low income group, in the shortest possible time.

Respectfully submitted,

EDWIN S. HAMILTON, Chairman.
RAYMOND L. ZECH.
C. B. CONKLIN.
RALPH T. B. TODD.
EDWARD H. MCLEAN.
IVAN FAWCETT.

Report of Reference Committee on Executive Session

Dr. Albert F. R. Andresen, Chairman, presented the following report, which was adopted on motion of Dr. Andresen, seconded by several, and carried:

The Committee has carefully considered the resolution of Drs. Clark Bailey and J. B. Lukens, of Kentucky, complimenting the Subcommittee on Expenditures of the Congress of the United States in exposing activities of certain employees of the United States government in their efforts to socialize medicine, and with the addition of one word has unanimously recommended that the resolution be approved by the House of Delegates at its Executive Session. The resolution now reads as follows:

WHEREAS, Last July there was printed a report of the Subcommittee on Expenditures of the House of Representatives of the Congress of the United States whereby it was revealed that certain employees of the United States government had vigorously headed a program whereby an organized nationwide effort was being made to cause the people of this country to accept the idea of compulsory health insurance as proposed in the Wagner-Murray-Dingell Bill; therefore be it

Resolved, That the House of Delegates of the American Medical Association commend the action of this committee in exposing the activities of those government employees who would destroy medicine as we know it and the ideals which we as members of the American Medical Association and all patriotic citizens have upheld; and be it further

Resolved, That we congratulate this committee for its efforts in upholding the ideals of democracy and request that a copy of these resolutions be sent to it.

Respectfully submitted,

ALFRED F. R. ANDRESEN, Chairman.
STEPHEN E. GAVIN.
PATRICK E. GEAR.
RALPH B. EUSDEN.
FRED H. MULLER.
JAMES L. WHITEHILL.
HUGH P. SMITH.
GEORGE P. JOHNSTON.

Tuesday Afternoon

On motion of Dr. Mather Pfeifferberger, Illinois, seconded by several and carried, the House rose from Executive Session at 4:25 p. m., to meet immediately in general session.

Report of Reference Committee on Medical Service

Dr. E. S. Hamilton, Chairman, presented the following report, which was adopted section by section and as a whole on motions of Dr. Hamilton, duly seconded and carried after discussion:

1. *Resolution on Proper Integration of Training of Nurses*.—Inasmuch as this problem is now under consideration by the Interim Committee, which has made a preliminary report and will make a final report in June 1948, this resolution is referred to that committee, with a recommendation that it study it further.

2. *Report of Committee on Rural Medical Service*.—After a careful review of the report in the brochure presented by the Committee on Rural Medical Service, your Reference Committee wishes, at this time, to commend this work. It is astounded

at the extent of the work and the active cooperation that is being given in all the states of the nation and wishes to recommend that this work be continued and expanded as the committee sees fit.

Again your reference committee wishes to commend the Committee on Rural Medical Service for a magnificent piece of work.

3. *Resolutions on Red Cross Blood Program*—Your Reference Committee recommends to the House of Delegates continued approval of the "approval in principle resolution" passed in June 1947 in regard to the establishment of blood banks by the American Red Cross, provided that the American Red Cross accept the following principle: To insure safety to recipients, the responsibility for technical details must rest on properly trained personnel under the control of local or state medical societies.

The Committee further recommends that the American Red Cross be asked to accept a permanent committee from the American Medical Association to coordinate the medical work of the Red Cross.

Respectfully submitted,

EDWIN S. HAMILTON, Chairman.
RAYMOND L. ZECH.
C. B. CONKLIN.
RALPH T. B. TODD.
EDWARD H. MCLEAN.
IVAN FAWCETT.

Presentation and Address of Dr. Archer C. Sudan

Dr. E. L. Henderson, Chairman, Board of Trustees, presented to the House Dr. Archer C. Sudan, the first recipient of the General Practitioner Medal, who spoke as follows:

Mr. Speaker and Members of the House of Delegates:

I am glad for the opportunity to express my deep appreciation for the extreme honor that you have conferred on me. At the same time I have in my heart a feeling that there are many thousand other general practitioners who are equally as deserving of this honor. In receiving it, it is with a feeling that I do so for all of those.

I should like to say that some of my friends, I am informed, have arranged a little reception to which all the members of the Board of Trustees and the House of Delegates are invited. I should like the opportunity to shake the hands of as many of you as possible.

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Mather Pfeifferberger, Illinois, and carried, the House adjourned at 4:35 p. m.

World Medical Association

The General Assembly of the World Medical Association, which met in Paris, France, in September 1947, decided to locate the head office of the association in North America and authorized the chairman of the council, Dr. T. C. Routley of Canada, and Dr. Louis Bauer of New York, council representative from the American Medical Association, to select the site, subject to the approval of the American and Canadian medical associations. After careful consideration, it has been decided to locate the office in New York, in excellent quarters which have been secured in the building of the New York Academy of Medicine at 2 East 103d Street.

The council will meet in New York on April 26, 27, 28 and 29, 1948, at which time it is expected that the new quarters will be available.

Following the meeting of the council, the members will be guests of the American Medical Association, the Mayo Foundation, the University of Minnesota and several other universities for a ten day tour which will take them as far west as Minneapolis.

Official Notes

CHANGE IN FELLOWSHIP DUES AND SUBSCRIPTION TO THE JOURNAL

This is to notify all concerned that the House of Delegates at the Cleveland Interim Session, Jan. 6, 1948, increased the annual Fellowship dues and subscription to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION to \$12 effective Jan. 1, 1948.

CENTENNIAL RECORDINGS

Phonograph recordings of the sermons delivered by Monsignor Fulton J. Sheen, Dr. Joshua Loth Liebman and Rev. Ralph Cooper Hutchison at the Atlantic City Centennial session of the American Medical Association have been made available by the Bureau of Health Education. The sermons, contained in three records that are packaged in a special album, may be obtained from the Order Department on remittance of \$6. A pamphlet containing reproductions of the sermons as they appeared in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is available free of charge for single copies from the Bureau of Health Education.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 9-10. Dr. Ronald G. Anderson, 535 North Dearborn St., Chicago 10, Secretary.

National Conference on Rural Health, Chicago, Palmer House, Feb. 6-7. Dr. F. S. Crockett, 535 N. Dearborn St., Chicago 10, Chairman.

American Academy of Orthopaedic Surgeons, Chicago, Palmer House, Jan. 24-29. Dr. Harold B. Boyd, 869 Madison Ave., Memphis, Tenn., Secretary.

American College of Allergists, New York, Hotel Pennsylvania, March 12-14. Dr. Fred W. Wittich, 423 LaSalle Medical Bldg., Minneapolis 2, Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, Philadelphia, Feb. 26. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

American Society of Biological Chemists, Atlantic City, March 14-19. Dr. Otto A. Bessey, Public Health Research Institute, New York 19, Secretary.

Central Surgical Association, Chicago, Drake Hotel, Feb. 19-21. Dr. Walter G. Maddock, 250 E. Superior St., Chicago 11, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, Palmer House, March 2-5. Dr. Willard O. Thompson, 30 N. Michigan Blvd., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, Hotel Adolphus, March 15-18. Dr. Glenn D. Carlson, 1133 Medical Arts Bldg., Dallas, Secretary.

International Postgraduate Medical Assembly of Southwest Texas, San Antonio, Municipal Auditorium, Jan. 27-29. Dr. W. W. Bondurant Jr., 711 E. Houston St., San Antonio, President.

Michigan Postgraduate Clinical Conference, Detroit, Book-Cadillac Hotel, March 10-12. Dr. H. H. Cummings, 2014 Olds Tower, Lansing 8, Chairman.

Mid-South Postgraduate Medical Assembly, Memphis, Tenn., Feb. 10-13. Dr. Arthur F. Cooper, 1479 Carr Ave., Memphis, Secretary.

Missouri State Medical Association, St. Louis, Hotel Jefferson, March 14-17. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Exec. Secretary.

National Conference on Medical Service, Chicago, Palmer House, Feb. 8. Dr. Edward F. Sladek, 232 E. Front St., Traverse City, Mich., Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Municipal Auditorium, Feb. 23-26. Dr. Max M. Green, 1430 Tulane Ave., Room 105, New Orleans 13, Secretary.

Pacific Coast Surgical Association, Los Angeles, Ambassador Hotel, Feb. 24-28. Dr. Carleton Mathewson Jr., Stanford Univ. Hospital, San Francisco, Secretary.

Southern Society for Clinical Research, New Orleans, Jan. 27. Dr. Thomas Findley, Ochsner Clinic, New Orleans 15, Secretary.

Tri-States Medical Association of the Carolinas and Virginia, Charleston, S. C., Fort Sumter Hotel, Feb. 9-10. Dr. James M. Northington, 306 N. Tryon St., Charlotte 2, Secretary.

Washington Letter

(From a Special Correspondent)

Jan. 20, 1948.

Dr. Hawley to Head Blue Cross and Blue Shield

Dr. Paul R. Hawley, former medical director of the Veterans Administration, was appointed chief executive officer of the Blue Cross and Blue Shield prepaid health service plans, two privately operated organizations with membership estimated at 36,500,000. His headquarters will be in Chicago. The appointment takes effect April 1. Dr. Hawley accepted the posts at a dinner at the Hotel Statler. He will continue to spend some time in Washington in a consulting capacity as a special assistant to veterans administrator Carl Gray and as head of a special committee formed by Secretary of Defense Forrestal to unify medical services in the armed forces. He also directs another medical group surveying the medical and sanitation phases of the national mobilization program for the National Security Resources board. Dr. Hawley said that he is opposed to government control of medicine and that he has seen government medicine in operation in other countries, commenting: "I know what government control does to medicine. I want no part of it for our people." Government doctors tend to forget the humanities in medicine, he said, with the result that the physician-patient relationship is affected. The Blue Cross, approved by the American Hospital Association, comprises ninety-one nonprofit hospital service prepayment plans. The Blue Shield, approved by the American Medical Association, includes forty-eight nonprofit medical-surgical service prepayment plans. Paying tribute to Dr. Hawley at the dinner were Dr. Edward L. Bortz of Philadelphia, President of the American Medical Association, and Graham L. Davis of Battle Creek, Mich., president of the American Hospital Association.

Dr. Paul B. Magnuson Heads Veterans' Medical Department

Carl R. Gray, veterans administrator, appointed Dr. Paul B. Magnuson of Chicago medical director of the Veterans Administration to succeed Dr. Paul R. Hawley, who resigned January 1. Dr. Magnuson is a native of St. Paul and was professor of surgery at Northwestern University Medical School before joining the agency in January 1945. He had been second in command of the agency medical department, and Mr. Gray said that Dr. Magnuson, with Dr. Hawley, "played a large role in affiliating more than half of the Veterans Administrations' one hundred and twenty-six hospitals with Class A medical schools over the country and in establishing the agency's residency training program." Since September Dr. Magnuson has been the agency's acting chief of professional services. Dr. Hawley will continue to assist in carrying out the veterans' medical program.

Dr. Overholser Charges Mental Hospitals are "Financially Starved"

In comment on the report of Dr. Samuel B. Wortis on conditions at Gallinger Hospital's psychopathic division, Dr. Winfred Overholser, superintendent of St. Elizabeths Hospital, declared that there has been "too much systematic financial starvation of public mental hospitals in this country." He said that mental patients must be regarded as medical problems and not as objects of charity. He advocated better medical techniques, better facilities, better nurses and more adequate financing.

Research Hospital to Include Beds for Patients with Cancer

Federal Security Administrator Oscar R. Ewing announced that the proposed five hundred bed research hospital in Bethesda, Md., will include accommodation for 150 patients with cancer. It is planned to give physicians their first real chance to make an intensive study of victims of chronic cancer. Mr. Ewing, in his statement prepared for delivery to the House of Delegates

of the American Medical Association at the interim meeting in Cleveland, asked the American Medical Association for the cooperation of organized medicine on noncontroversial health projects. He said that one of the most pressing American health problems was the proper distribution of hospitals and medical personnel.

Medical Legislation

STATE LEGISLATION

Massachusetts

Bills Introduced.—H. 69, to amend the law relating to the practice of dentistry, proposes that no corporation shall conduct a dental office and no person shall conduct a dental office under any name other than that of the dentist actually owning the practice. H. 91, to amend the medical practice act, proposes to provide for the revocation of the certificate of registration of any physician guilty of the use of narcotic drugs in any way other than for therapeutic purposes. H. 92, to amend the law relating to the inspecting of colleges, universities and medical schools, proposes the appointment of an approving authority to inspect such institutions from time to time and to notify the trustees or governing bodies of such institutions in the event that they do not meet the necessary requirements for approval. H. 104 proposes an act to provide for the development and administration of a hospital construction program. Among other things, this proposal defines "hospital" and "public health center," authorizes the commissioner of the state department of public health to apply for federal funds in a state hospital construction program and provides for the appointment of an advisory hospital council to advise and consult with the commissioner in relation to any construction operations. H. 106, to amend the law relating to the licensing of hospitals, sanatoriums, convalescent and nursing homes, proposes that certain safety features must be included in such institutions before a license will be issued. H. 110, to amend the law designating certain diseases which physicians must report to the department of public health, proposes that the department may designate other diseases not specifically mentioned in the statute which shall be reported by physicians but which shall not thereby be deemed to have been declared diseases dangerous to the public health. H. 111, to amend the law relating to the adulteration, misbranding, etc. of dangerous drugs, proposes, among other things, to define harmful drug as including amidopyrine, benzedrine, cantharides, cinchophen, digitalis, dinitroresorcinol, dinitrophenol, ergot, estrogen, natural or synthetic, barbituric acid, chloralhydrate, paraldehyde, sulfonamide drugs, thyroid, oil of croton, oil of pennyroyal, oil of sassa and oil of tansy and then proposes that no harmful drug as defined herein shall be sold at retail or dispensed or given away to any person except on the written prescription of a physician, dentist or veterinarian nor shall a prescription therefor be renewed or refilled by a pharmacist if the prescription bears any indication that it is not to be so renewed or refilled. H. 310 proposes a law for a voluntary system for payment of hospital, surgical operation, sickness and bodily injury and maternity benefits to employees. H. 385 proposes that whoever experiments or operates in any manner whatsoever on any living dog or cat for any purpose other than the healing, curing or sterilizing of said dog or cat shall be punished by a fine or imprisonment or both. H. 414 proposes the creation of a hospital lien on any patient's cause of action to the extent of support, treatment or medical care which the hospital has rendered to such patient. H. 1349 and S. 44 propose that any person who was a student at the College of Physicians and Surgeons prior to June 30, 1946 and who receives a degree of doctor of medicine therefrom prior to June 30, 1949 shall be eligible to be an applicant for registration as a qualified physician, shall be examined for such registration by the board of registration in medicine and shall be subject to and have the benefit of all pertinent provisions of law relative to such eligibility and examination.

Mississippi

Bill Introduced.—H. 5, to amend the law relating to procedure for committing persons to state mental institutions; proposes that no person shall be admitted to a state mental institution except on a satisfactory report from two reputable licensed physicians.

New York

Bills Introduced.—A. 99, to amend the labor law, proposes to permit recovery under the unemployment insurance act for unemployment due to sickness or accident disability which has been certified under oath by a physician or surgeon duly licensed to practice in the state of New York. A. 100, to amend the labor law, proposes to extend the coverage under the unemployment insurance law to employees of charitable, scientific, literary or educational organizations.

Rhode Island

Bill Introduced.—H. 513, to amend the sales and use tax act, proposes to exempt therefrom hospitals not operated for profit and businesses engaged in the sale and storage of medicines and medical supplies.

GOVERNMENT SERVICES

ARMY, NAVY AND AIR FORCE

BOARD TO STUDY UNIFICATION OF MEDICAL SERVICES

Secretary of Defense James Forrestal has listed some of the problems which he desires to have considered by the recently appointed Committee on Medical and Hospital Services of the Armed Forces. Dr. Paul R. Hawley, formerly chief medical director of the Veterans Administration, is chairman of the committee; the Surgeons General of the Army and Navy and the Air Surgeon are the other members. Rear Admiral Joel T. Boone (MC), U.S.N., inspector, medical activities, Pacific Coast, has been called to Washington to act as executive secretary of the committee. In general, the Secretary of Defense desires a thorough, objective and impartial study of the medical services of the Armed Forces with a view to obtaining, at the earliest possible date, the maximum degree of coordination, efficiency and economy in the operation of these services. The list, Mr. Forrestal said, is not meant to be exclusive or in any way to limit the avenues of the inquiry in furtherance of the general objective. On the contrary, it is intended to be suggestive of the kind of problems which he believes must be tackled.

Among the specific problems outlined by Mr. Forrestal were the following:

1. Improvement in the utilization of the existing hospital facilities of the several medical services. This will include consideration of the number of hospital beds required in each geographic area to meet the collective needs of the three services; a study of which hospitals are so located as to make it feasible for them to serve more than one of the departments, and a determination as to which hospitals, if any, should be closed, placed in standby status or disposed of as surplus. It will also require an examination and reevaluation of the standards for hospitalization and an inquiry into the possibility of using other facilities, in lieu of regular hospitals, for minor convalescence, periodic medical examinations and the like.

2. Coordination of current plans of the medical services for the construction of any new hospital facilities in the future.

3. Methods for improving the organization and administration of the several medical departments in the operation of both their hospital and medical programs, including the possibilities of consolidation or coordination of certain activities and functions thereof and the reduction of the combined overheads of the medical services of the Armed Forces.

4. Coordination or consolidation of the medical research programs of the medical services, and the maximum joint use of research facilities.

5. Coordination or consolidation of medical training programs of the medical services of the Armed Forces. This should include an inquiry into the possibilities of joint utilization of service schools, the coordination of postgraduate training, the provision by one service for all services of general training or training in specialized fields, joint preparation of medical bulletins and specialized courses and common library facilities.

6. Allocation to one service of the responsibility for providing all hospitalization and medical care for all services in certain fields of medicine as, for example, in the fields of tropical medicine, neuropsychiatry, radiologic injuries, prosthetics and serious disorders of the ear and eye.

7. Development of common standards and procedures among the medical services with respect to the physical and mental requirements for entrance into the services and for disability discharges; preventive medicine, and the organization, administration and operation of hospitals.

8. Improvement and standardization of medical records and nomenclature; cost accounting systems; forms; specifications for supplies and equipment, and regulations.

9. Maximum utilization of qualified medical personnel of the Armed Forces. Consideration should be given to the joint use of highly specialized personnel, to the possibility of interchange of medical personnel among the medical services depending on requirements and facilities for such personnel, to the relief of qualified physicians from administrative responsibilities and to providing them with greater opportunity for exclusive attention to the practice of their profession.

In conducting this study the committee is authorized to consult with such persons in the Armed Forces as it may wish and to call as witnesses such individuals or organizations from outside the regular military establishment as the committee desires. Mr. Forrestal said that although he would like a report at the earliest practicable date he does not want haste to detract from the submission of a thorough, comprehensive study. He believes that few problems facing the national military establishment have the importance and urgency of the matters which the committee is being asked to study.

PUBLIC HEALTH SERVICE

EXPERIMENTAL BIOLOGY AND MEDICINE INSTITUTE

The establishment of an Experimental Biology and Medicine Institute in the National Institute of Health of the U. S. Public Health Service has been announced by the Federal Security Administrator. The new research institute will combine the functions of the division of physiology and the pathology and chemistry laboratories and will permit greater coordination of scientific investigations.

Formation of the institute is part of a wider organization of the National Institute of Health, Thomas Parran, Surgeon General of the Public Health Service, explained. Four other divisions and laboratories engaged in scientific research also will be consolidated into two additional institutes. All of them will be modeled after the National Cancer Institute.

Dr. William Henry Sebrell Jr., chief of the division of physiology, has been named director of the new institute. He will also serve as associate director of the National Institute of Health. The director of the new institute is an authority in the field of nutrition who has been with Public Health Service since his graduation from the Virginia School of Medicine in 1925. He served under Dr. Joseph Goldberger, pioneer nutri-

tionist, and after Dr. Goldberger's death in 1929 was placed in charge of nutrition studies at the institute. In 1940 he received the Mead Johnson Award of the American Institute of Nutrition for research on vitamin B complex and in 1946 was awarded the research medal of the Southern Medical Association. In 1945, at the request of the War Department, Dr. Sebrell spent three months in Europe as consultant on nutrition to the U. S. Army's Military Government Public Health Staff. For his outstanding services he was awarded the Legion of Merit.

SYMPOSIUM ON VENEREAL DISEASE

The Syphilis Study Section of the National Institute of Health, a group of consultants organized for the purpose of promoting research in the field of venereal disease, announces a symposium on "Recent Advances in the Study of Venereal Diseases," to be held in the Commerce Building, Washington, D. C., on April 8 and 9. Interested persons are invited to attend. Copies of the program will be sent on request. Inquiries should be addressed to Dr. Frank W. Reynolds, Executive Assistant, Syphilis Study Section, Division of Research Grants and Fellowships, National Institute of Health, Bethesda 14, Md.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Epidemic in Los Angeles.—The Los Angeles City Health Department in the *Bulletin* of the Los Angeles County Medical Association January 15 reported a "widespread outbreak of some sort of upper respiratory infection in Los Angeles." Clinical symptoms vary too much to implicate any single specific disease. Both upper respiratory and gastrointestinal symptoms are reported. The disease, the report continues, is probably caused by a virus and has a short incubation period (two days plus).

ILLINOIS

State Bacteriologists Meet.—The Society of Illinois Bacteriologists will meet Friday, January 30, at 6:30 p. m. in the Museum of Science and Industry, Chicago. Among the speakers will be Dr. Guy P. Youmans, Chicago, on "Streptomycin in the Treatment of Tuberculosis" and Dr. James A. Schoenberger, Chicago, on "Results of Vaccination Against Influenza During the Spring of 1947."

Chicago

Graduate Course in Pediatrics.—Michael Reese Hospital will conduct a postgraduate course in recent advances in pediatrics May 3-15. The course is divided into two week-long sections, (1) The Full Term and Premature Infant in Health and Disease and (2) Diagnostic and Therapeutic Measures in General Pediatrics. Tuition is \$50 per section. The size of the class is limited. For information address Dr. Samuel Soskin, Dean, Michael Reese Hospital Postgraduate School, 29th Street and Ellis Avenue, Chicago 16.

Museum Plans Medical Exhibits.—The Museum of Science and Industry in Jackson Park has established a six to eight year exhibit construction program in the fields of the medical sciences. Dr. Andrew C. Ivy, vice president of the University of Illinois, has been appointed head of the program. The university and the museum will cooperate, and Dr. Ivy's committee will assume responsibility for the development of a general plan of exhibit subjects. Dr. Thomas G. Hull, director of the Scientific Exhibit of the American Medical Association and assistant professor of public health at the University of Illinois, will be executive director of the Committee on Health Exhibits. The yearly traffic at the museum is a million and a half visitors from all parts of the country.

Neurology Lecture Series.—Harlow W. Ades, Ph.D., visiting professor in the Institute of Neurology of Northwestern University Medical School, is conducting a series of four lectures on "Central Auditory and Cortical Function," all meetings convening at 4 p. m. in room 641 of the medical school. The lecture on January 29 will deal with learned responses to auditory stimuli and on February 5 with the problem of learning in relation to structure and function. Dr. Ades is assistant professor of neuroanatomy and chairman of the anatomy department, Emory University School of Medicine, Atlanta, Ga. His appointment at Northwestern is the first under a recently established annual visiting professorship in the Institute of Neurology, sponsored by the Rockefeller Foundation.

MASSACHUSETTS

Gift to Medical Center.—A gift of \$300,000 was received Nov. 30, 1947, by the Bingham Associates Fund which supports the New England Medical Center, Boston, from Jacob Ziskind, Fall River, an industrialist. Leonard Carmichael, Ph.D., president of Tufts College and chairman of the fund, said that the money would be used to purchase a medical research building for the center. Participating institutions include the Joseph H. Pratt Diagnostic Hospital, Boston Floating Hospital, Boston Dispensary and Tufts Medical School, the teaching base.

Death of Pioneer Nutritionist.—Miss Frances Stern, pioneer nutritionist and founder of the Food Clinic of the Boston Dispensary, died Dec. 23, 1947, aged 74, following a heart attack at her home in Newton. The clinic was named the Frances Stern Food Clinic in her honor, and the Frances Stern Nutrition Fund for Tufts College Medical School, Boston, was established by friends. The clinic under Miss Stern's direction has served as a teaching and research center for Tufts College Medical School, Simmons College School of Social Work, Framingham Teachers College and Regis College.

MICHIGAN

Rheumatic Fever Centers in Wayne County.—The Michigan State Medical Society's Committee on Rheumatic Fever Control, with the financial assistance of the Michigan Society for Crippled Children and Disabled Adults, Inc., has approved the opening of sixteen new Rheumatic Fever Control Centers in Wayne County. The program will be under the joint operation of the state and Wayne County medical societies' committees on rheumatic fever control.

Grant for Group Therapy Studies.—The U. S. Public Health Service Commission on Mental Hygiene has made a grant of \$18,030 to aid Wayne University, Detroit, in evaluating information gained by observation of group therapy work for children. Fritz Redl, professor of social work in the School of Public Affairs and Social Work, will direct the research for one year beginning next month. The evaluation will cover four research problems: (1) criteria for group composition; (2) the phenomenon of contagion and aggravation in therapy groups; (3) methodology of recording for use in therapy groups, and (4) the factor of timing in the exposure to therapy groups.

Seminar in Physical Medicine.—Physical Medicine will be the subject of a one day seminar Wednesday, February 4, in Bay City, at the Wenonah Hotel, with the following lectures:

H. Barbara Jewett, Detroit, An Occupational Therapy Technician in General Practice.

Dr. Frederick B. House, Ann Arbor, Management of Cerebral Palsy.

Dr. Max K. Newman, Detroit, Physical Medicine in Vascular Disease of the Extremities.

Dr. Walter M. Solomon, Cleveland, Physical Medicine in Arthritis.

The new department of physical medicine at Bay City's General Hospital will be inspected by registrants at 5 p. m. prior to dinner at the hotel. In the evening Dr. Louis B. Newman, Veterans Administration Hospital, Hines, Ill., will speak on "The Management of Paraplegics—Spinal Cord Injuries." Sponsors of the seminar are the Bay County Medical Society, the Michigan State Medical Society's Committee on Postgraduate Medical Education, Wayne University and the Bay City General Hospital.

MINNESOTA

Memorial to Dr. O'Brien.—A memorial to the late Dr. William A. O'Brien, director of postgraduate medical education and professor of public health at the University of Minnesota School of Medicine, Minneapolis, has been set up to provide funds to be used to furnish facilities at the Mayo Memorial Medical Center for continuation study programs such as Dr. O'Brien developed. Dr. O'Brien died Nov. 15, 1947.

MISSISSIPPI

First Physician Under Program Enters Rural Practice.—Dr. Lloyd Z. Broadus, who completed medical training at the University of Utah in 1947, is the first young physician to complete training under Mississippi's scholarship loan program and has entered general practice at Purvis, a community of one thousand persons. A total of one hundred and five medical students in Mississippi are now receiving benefits of the medical education scholarship loan. About 69 per cent of the total are veterans of World War II.

NEW MEXICO

Lecture on Cancer.—Dr. Charles L. Martin, professor of radiology, Southwestern Medical College, Dallas, Texas, will address the New Mexico Clinical Society at its January 28 meeting at the Veterans Hospital, Albuquerque, at 8 p. m. Dr. Martin will present a lecture with colored films on "Treatment of Cancer of the Face, Lip, Mouth and Metastatic Lymph Nodes with Radiation." The society, organized in November 1946 by a group of Albuquerque, Santa Fe and Los Alamos physicians, sponsors a monthly lecture by leading authorities in the fields of clinical medicine and surgery.

NEW YORK

Lecture for Suffolk County.—Dr. George E. Anderson, Brooklyn, will speak on "Diabetes Mellitus" before the Suffolk County Medical Society at 8 p. m. January 28 at the Patchogue Hotel, Patchogue. The lecture was arranged by the Medical Society of the State of New York with the cooperation of the New York State Department of Health.

Consultation Services for Health Departments.—The State Department of Health plans to establish by February 1 five state regions with offices located in Buffalo, Rochester, Syracuse, Albany and New York, and a sixth region with headquarters also in New York to serve the metropolitan area. The regional offices are to provide consultation service to the staff of the district, county and city health departments within

the region; assistance in program planning, development and operation; guidance to local health departments, and observations for the state department of health of the local health departments in the region. Direct services to local residents will not be given by any of the personnel assigned to regional offices, except in the unorganized district on a temporary basis until permanent plans have been made. The supervisory functions previously carried by the district office will become functions of the regional office, and as soon as county health departments take over the functions of the state district offices the state districts will be eliminated. Then the regional offices will assume the duties of the district offices not covered by county and city health departments.

New York City

Record High Birth Rate.—According to the preliminary report of the city health department during the past year, 170,469 births set an all-time high record, with a birth rate of 21.8 per thousand population, as compared to 19.6 for 1946. The record number of births was accompanied with an all time low record in infant mortality (26.5 per thousand live births) and a maternal mortality rate of 1.1 per thousand live births. Deaths from cancer rose sharply. Although the death rate for tuberculosis continued to decline, it was the leading cause of death among persons in the 15 to 24 age group. Poliomyelitis cases were the lowest in number since 1942. Of the 11 children who died (January through November) of diphtheria, 9 had never received toxoid.

Cancer Research at Columbia.—Columbia University has received funds totaling \$28,376 from the American Cancer Society, Inc., for research on cancer. One gift, \$7,368, was for the continued study of the application of the isotope technic to the problems of clinical medicine in man. This project is being carried on by the department of biochemistry. Other projects provided for in the funds were research on cells in vitro and research on nucleic acid of normal and cancerous tissues, both by the department of surgery, and a study of animal tissues by the department of medicine. Columbia also announced receipt of \$2,250 from the New York City Cancer Committee of the American Cancer Society for clinical research on gynecologic cancer, the work to be carried on by the department of obstetrics and gynecology.

Survey of Employees with Heart Disease.—A joint survey of persons in industry with heart disease to determine the appropriateness of their jobs and to offer guidance to those in unsuitable vocations was initiated by New York University College of Medicine and the New York State Department of Education January 8. The survey will be carried out in the Bellevue Hospital Cardiac Clinic. University doctors will continue to be responsible for the care of the patients as well as for the evaluation of their physical capacities. Added to the clinic's staff will be a group of interviewers from the state Office of Vocational Rehabilitation. An important aim of the survey will be to develop data which will help to demonstrate that persons with cardiac disorders can be employed more widely than at present with practically no risk to themselves or their employers.

OHIO

Personal.—Dr. Carl A. Wilzbach, Cincinnati, has received an award from the American Cancer Society for his activities in the last ten years in behalf of cancer control. Dr. Wilzbach and Dr. Lawrence A. Pomeroy of Cleveland helped in starting the Ohio unit of the society.

Awards for Public Service.—The Public Health Federation of Cincinnati in December presented two scrolls and engraved gold keys as awards of honor to two of its members. Dr. William Muhlbarg, former medical director of the Union Central Life Insurance Company, and Mr. Bleeker Marquette were cited for distinguished service to the cause of public health in greater Cincinnati for their "effort and outstanding achievement over a period of many years." Among other activities, Dr. Muhlbarg has served the federation as president and president of the board and Mr. Marquette has served as executive secretary.

Grants for Development of Psychiatry.—The department of psychiatry at the University of Cincinnati College of Medicine has been awarded a \$175,000 grant by the Rockefeller Foundation, effective January 1. The grant covers a five year period and is to be used for the development of psychiatry under Dr. Maurice Levine, professor and head of the psychiatry department. Two other grants have been awarded to the department this year: The first was \$28,800 from the Commonwealth

Foundation for use in joint projects of the departments of psychiatry and internal medicine under Drs. Levine, Marion A. Blankenhorn, professor of medicine and head of the department, and Eugene B. Ferris, associate professor of medicine. The other was \$22,150 from the U. S. Public Health Service for use under the Mental Health Act passed by Congress.

OKLAHOMA

Disease Prevention Campaign.—The Garfield County Medical Society in cooperation with school officials and the state department of health began a campaign for disease prevention Dec. 5, 1947 by inoculating 1,500 school children in Enid for diphtheria and pertussis. Plans are under way for carrying the campaign to outlying towns and school districts in the county. Sixteen physicians, all members of the society, reported for duty. Participation is voluntary on the part of both physicians and parents. The physicians are making no charge for their services, and the state is furnishing the serum without charge. Children of preschool age may also be included.

TEXAS

University News.—Dr. Hans Molitor, director of the Merck Institute for Therapeutic Research, will lecture January 26 at the University of Texas Medical Branch, Galveston, on "The Pharmacology of Antibiotics."—Mr. Jack Still, professor of biochemistry, University of Sydney, Australia, recently visited the Medical Branch to survey studies on enzyme chemistry. Mr. Still is a Rockefeller traveling fellow and plans to work at Columbia University, New York.—Wilbur A. Selle, Ph.D., professor of physiology and director of the Laboratory of Medical Physics, has been appointed visiting professor of physiology at the University of Arkansas School of Medicine, Little Rock, Ark. He will return to direct a graduate course in physical medicine March 1-5 at the University of Texas Medical Branch.

VIRGINIA

Society News.—The Virginia Pediatric Society has elected Dr. Thomas A. Gibson, Winchester, president, and Dr. E. Berkeley Neal, Roanoke, secretary-treasurer.

Motorized Tuberculosis Clinics.—Three mobile clinics, operated by the state department of health throughout the hundred counties of Virginia, keep up a year-round town to town campaign against tuberculosis. Each clinic, which is assigned to roughly one third of the state, visits each county in its section twice a year. The clinics are set up to take six hundred 70 mm. films a day and seventy-five chest pictures 14 by 17 inches (35.56 by 43.18 cm.). The state program began in 1930.

First Stoneburner Memorial Lecture.—Dr. Perrin H. Long, professor of preventive medicine at Johns Hopkins University School of Medicine, Baltimore, will deliver the first Lewis T. Stoneburner III lecture in internal medicine at the Medical College of Virginia, Richmond, in Baruch Auditorium January 30 at 8 p.m. on "Choice of Sulfonamide Drugs and Antibiotic Agents in the Treatment of Infections." The lecture-ship was established at the Medical College of Virginia by the friends of Capt. Lewis T. Stoneburner III who were members of the 45th Hospital Division with him during World War II (THE JOURNAL, Dec. 13, 1947, p. 1017).

HAWAII

Enlarge Tuberculosis Hospital.—Leahi Hospital, Honolulu, the only institution for the care and treatment of tuberculosis on the island of Oahu, is undergoing a \$4,300,000 construction program, which will give the main hospital a bed capacity of 916 as compared with that of 488 before construction began. Two ward units providing 248 beds were to have been opened in December. The hospital began to function as a tuberculosis sanatorium in 1906. It is a nonprofit corporation chiefly financed by the Territory of Hawaii.

Cardiac Clinic Opened.—St. Francis Hospital, Honolulu, opened a cardiac clinic in its new wing in August. Set up in accord with the standards of the American Heart Association, it maintains a full time social service worker who deals with conditions such as the patient's home situation, occupation or point of view, which may require adjustment in order to make medical treatment effective. The Honolulu Chamber of Commerce granted \$3,000 for the purchase of equipment and pamphlets to be used in the education program for the patients. Dr. F. Bernard Schultz is director.

GENERAL

Magazine for Diabetic Persons.—The American Diabetes Association began publication of the *ADA Forecast*, a magazine for diabetics, in January 1948. Its purpose is to give the physician an additional aid in the treatment of his diabetic patient by giving the patient helpful articles by authorities in the field and an understanding for the need of close cooperation with his physician. The first number of the *Forecast* includes articles by Dr. Elliott P. Joslin, Boston, Dr. Herman O. Mosenthal, New York, and Dr. Joseph H. Barach, Pittsburgh.

Electroencephalographers Meet.—The Western Society of Electroencephalography held its first scientific meeting at the University of California Hospital, San Francisco, Nov. 8, 1947. A constitution was adopted, which offers membership to physicians actively engaged in the specialty. Investigators in scientific fields related to electroencephalography are eligible for associate membership. Dr. Robert B. Aird, San Francisco, was elected chairman and Dr. Nicholas A. Berceel, Los Angeles, secretary-treasurer. The next meeting will be held in San Francisco April 10-11 directly preceding the annual meeting of the California Medical Association.

Meeting on Physical Medicine.—The Midwestern section of the American Congress of Physical Medicine will hold its annual meeting February 26-27 at the Veterans Administration Hospital, Hines, Ill. A seminar on spinal cord injuries will follow registration at 10 a. m. Physicians associated with Northwestern University Medical School, the University of Illinois College of Medicine, Chicago, and the Veterans Administration Hospital will appear on the program. All sessions will be open to physicians, other professional personnel and their guests. Other subjects to be discussed on Friday include physical medicine in relation to peripheral vascular lesions, peripheral nerve injuries, fractures, amputations and arthritis, and psychosomatic problems of the severely disabled.

Special Society Elections.—The National Malaria Society at its meeting in Atlanta, Ga., in December elected Dr. E. Harold Hinman, Wilson Dam, Ala., president and Wendell D. Gingrich, Ph.D., Galveston, Texas, president-elect. Martin D. Young, Sc.D., Columbia, S. C., was reelected secretary-treasurer. At the annual meeting of the American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, Dr. Jacob Daley, New York, was elected president, Dr. Norman N. Smith, New Haven, Conn., secretary, and Dr. Benjamin H. Shuster, Philadelphia, treasurer. The American Chemical Society elected Linus C. Pauling, Sc.D., chairman of the division of chemical engineering of the California Institute of Technology, as president for 1948.

Report of Ella Sachs Plotz Foundation.—The twenty-fourth annual report of the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation lists twenty-six grants during 1947 to institutions or investigators, making a total of five hundred and seventy-six grants in the twenty-four years of the foundation's existence. The grants may be used for the purchase of apparatus and supplies needed for special investigations and for the payment of unusual expenses incident to special investigations but not for providing apparatus or materials ordinarily a part of laboratory equipment. Application for grants for the year 1948-1949 should be sent to Dr. Joseph C. Aub, Massachusetts General Hospital, Fruit Street, Boston 14. They must be in the hands of the executive committee before April 15, 1948.

Campaign to Raise Millions to Aid War Victims.—American Overseas Aid—United Nations Appeal for Children will launch a campaign in February to obtain \$60,000,000 to meet emergency needs of millions of children of war-stricken countries and to supplement assistance extended by agencies of the United Nations. American Overseas Aid is a federation of the major voluntary agencies for foreign relief, organized at the suggestion of President Truman and in answer to the increasing demands from American community leaders for unification of peacetime appeals for aid to wartime victims. Funds will be used by various agencies for food, medical care, medicines, clothing, shelter, rehabilitation, education and training of workers in emergency fields. American Overseas Aid itself does not conduct any relief operations. It serves as the medium for financing activities of the various agencies, screens and coordinates agency activities to insure sound and efficient operations and examines and audits records of all program expenditures.

Dr. Gradle Awarded Medal for Prevention of Blindness.—The first Pan American Medal of the National Society for the Prevention of Blindness in the United States was awarded January 10 to Dr. Harry S. Gradle, for many years

a leading ophthalmologist in Chicago. Dr. Gradle is now retired and living in California. The award was made in Havana, Cuba, during the third Pan American Congress of Ophthalmology, of which Dr. Gradle was the founder and first president. Dr. Baudilio Courtis, Buenos Aires, Argentina, made the presentation to Dr. Gradle in absentia; he was unable to be present because of ill health. The citation read: "For scientific contributions to knowledge about causes of blindness and impaired vision, for outstanding service in advancing education in ophthalmology, for distinguished leadership in founding the Pan American Association of Ophthalmology."

Dr. Gradle graduated from the Rush Medical College in 1906. He served as attending and later senior attending ophthalmic surgeon to Michael Reese Hospital, Chicago, and for several years he was chief of staff at the Illinois Eye and Ear Infirmary. He was active in many scientific societies and held a professorship at the University of Illinois College of Medicine.

Five Leading Causes of Death.—The federal security administrator has just announced that a new record low crude death rate was made in the United States in 1946, when the death rate was 10 per thousand population as compared with the previous lowest rate of 10.4 in 1942. These figures are for the continental United States and exclude stillbirths and deaths among armed forces overseas. The five leading causes of death were diseases of the heart, which caused 429,230 deaths, cancer and other malignant tumors (182,005), intracranial lesions of vascular origin (125,646), nephritis (81,701) and accidents, excluding motor vehicle (64,622). Deaths from diseases of the heart increased for the third consecutive year and accounted for 30.8 per cent of the total number of deaths. Cancer and other malignant tumors continued to increase in importance as a cause of death, producing 13 per cent of the total number of deaths in 1946. The number of deaths from the other major chronic diseases, including intracranial lesions of vascular origin, nephritis, diabetes mellitus, pneumonia, influenza and tuberculosis, decreased from the previous year. The number of deaths from diabetes mellitus was 34,731 as compared with 35,160 in 1945. Tuberculosis caused 50,911 deaths in 1946 as compared with 52,916 in 1945. Maternal mortality declined to a new low in 1946 despite an increase of about 20 per cent in the number of births. Maternal deaths decreased from 5,668 in 1945 to 5,153 in 1946. Deaths from accidents totaled 98,033, of which 33,411 were the result of motor vehicle accidents.

CORRECTIONS

Experiment in Cardiac Rehabilitation.—The Altro Work Shops, Inc., has undertaken an experiment in the field of cardiac rehabilitation, not "in the field of cardiac rehabilitation of the tuberculous" as stated in *THE JOURNAL*, January 10, page 123.

Dr. Nelson Directs Laboratory of Research Toxicology.—Norton Nelson, Ph.D., associate professor of industrial medicine at New York University College of Medicine, is the director of the Laboratory of Research Toxicology of the Institute of Industrial Medicine of the New York University-Bellevue Medical Center, and not Rose C. Nelson, Ph.D., as stated in *THE JOURNAL*, Dec. 27, 1947, page 1160.

Marriages

CHARLES MILTON CARPENTER, Rochester, N. Y., to Miss Christine Thackston of Greenville, N. C., Oct. 4, 1947.

WILLIAM H. ROSENBLATT, Louisville, Ky., to Miss Margaret Hart Dreyfus of Jackson, Miss., Nov. 20, 1947.

ROGER G. MAGRUDER, Charlottesville, Va., to Miss Eleanor Ruth Moseley of Quanah, Texas, Oct. 18, 1947.

WALTER FRANK DAUGHTREY JR. to Miss Virginia Brooks Manry, both of Courtland, Va., Sept. 27, 1947.

NEIL CARRINGTON PRICE to Miss Annie Elizabeth Wolfe, both of Orangeburg, S. C., Oct. 18, 1947.

RALPH PARR BAKER to Miss Frances Elizabeth Renwick, both of Newberry, S. C., Nov. 14, 1947.

NORMAN SOLLOD, Petersburg, Va., to Miss Phyllis Laurel Freed of Harrisonburg, Nov. 2, 1947.

EDGAR H. MYERS, Hemingway, S. C., to Miss Mary Carolyn Epps of Kingstree, Nov. 15, 1947.

JAMES GRAY PERKINS to Miss Shir'lee Anne Dillard, both of Portland, Ore., Sept. 14, 1947.

Deaths

William Austin O'Brien * St. Paul; born in Fairbury, Ill., Feb. 28, 1893; St. Louis University School of Medicine, 1913; interned at Mount St. Rose Sanatorium and St. John's Hospital in St. Louis; at one time practiced in Detroit, where he had been an assistant in the health department; served in the U. S. Army medical corps during World War I; in 1921 entered the University of Minnesota to do graduate work and in 1923 joined the faculty as an instructor in pathology; advanced to professor of preventive medicine and public health and director of postgraduate medical education; specialist certified by the American Board of Pathology; state chairman and member of the board of directors of the American Cancer Society; member of the Minnesota Pathological Society; formerly pathologist to the University Hospitals; radio spokesman on WCCO for the Minnesota State Medical Association since 1928 and for many years for the Minnesota Dental Association and the Minnesota Hospital Association; staff member of the School of the Air Station, KUOM, University of Minnesota, since 1940; author of a syndicated health column in newspapers; medical editor of the Newspaper Enterprise Association; died Nov. 15, 1947, aged 54.

Oliver William Welch * Homewood, Ala.; born in Talladega, Ala., Sept. 19, 1907; received his master's degree in public health from Harvard School of Public Health in June 1936; Harvard Medical School, Boston, 1933; interned at the Boston City Hospital and the Massachusetts General Hospital; specialist certified by the American Board of Internal Medicine; associate member of the American College of Physicians; member of the House of Delegates of the American Medical Association in 1947; served overseas in the medical corps, Army of the United States, during World War II; consultant in public health work for the Tennessee Valley Authority from July 1936 to June 1938; chief of the medical service at the Employees' Hospital of the Tennessee Coal, Iron and Railroad Company; died suddenly in Birmingham Oct. 21, 1947, aged 40, of acute coronary disease.

Walter Link Liefeld * Seaford, Del.; born in New Haven, Conn., in 1886; Cornell University Medical College, New York, 1910; fellow of the American College of Surgeons; served on the staffs of the Newark Eye and Ear Infirmary in Newark, Passaic General and St. Mary's hospitals in Passaic, N. J., the Hackensack (N. J.) Hospital, the Wilmington General, St. Francis, Delaware and Memorial hospitals in Wilmington; at the time of his death on the staffs of the Beebe Hospital in Lewes, Milford Memorial Hospital in Milford and the Peninsula General Hospital in Salisbury, Md.; died suddenly, Oct. 30, 1947, aged 61, of pulmonary embolism as he was preparing to perform an operation.

Henry W. Reiter * Shakopee, Minn.; born in Rockville, Minn., in 1863; University of Minnesota College of Medicine and Surgery, Minneapolis, 1893; for many years county coroner; served as city health officer; past president and secretary of the Scott-Carver Counties Medical Society; an affiliate Fellow of the American Medical Association; formerly member of the school board; chairman of the county draft board during World War I; for many years secretary of the local board of examining surgeons for the U. S. Pension Bureau; affiliated with Shakopee Hospital; for many years local physician for the Northwestern Railroad; died Oct. 30, 1947, aged 83, of coronary thrombosis.

Samuel Edgar Munson * Springfield, Ill.; born in Dawson, Ill., Aug. 25, 1866; Northwestern University Medical School, Chicago, 1893; past president, vice president, secretary and chairman of the section of medicine of the Illinois State Medical Society and for many years counselor of the Fifth District; past president of the Sangamon County Medical Society and the Central District Medical Society; fellow, formerly vice president and for many years member of the board of governors of the American College of Physicians; specialist certified by the American Board of Internal Medicine; affiliated with Springfield Hospital; died in Memorial Hospital Oct. 2, 1947, aged 81.

Walter August Bock, Chicago; Loyola University School of Medicine, Chicago, 1939; member of the American Medical Association; graduate of U. S. Army School of Aviation Medicine; assistant medical director, United Air Lines; served during World War II as captain in the medical corps and flight surgeon with the Army Air Forces on the African front, where he sustained in a bomber crash injuries that resulted in his retirement from active service; affiliated with Englewood and St. Anthony's hospitals; died in Mercy Hospital Nov. 7, 1947, aged 35, of Hodgkin's disease.

Charles Child Gildersleeve, Norwich, Conn.; Yale University School of Medicine, New Haven, 1896; member of the American Medical Association; past president of the Connecticut State Medical Society and the New London and Windham counties' medical societies; medical examiner for Norwich, Franklin and Lebanon; affiliated with the Day Kimball Hospital in Putnam and the William W. Backus Hospital; trustee of the Connecticut State Hospital, Middletown; past president of the Association of Yale Medical Alumni; died Nov. 1, 1947, aged 81, of arteriosclerotic heart disease.

Jay Perkins * Providence, R. I.; Harvard Medical School, Boston, 1891; an Affiliate Fellow of the American Medical Association; member of the Rhode Island Medical Society and the American Clinical and Climatological Association; for many years president of the Providence Tuberculosis League; served during World War I; director, Family Welfare Society, from 1906 to 1939; affiliated with the State Sanatorium, Wallum Lake, Charles V. Chapin Hospital, St. Joseph's Hospital and the Rhode Island Hospital, where he died Oct. 18, 1947, aged 83, of arteriosclerotic heart disease.

Thomas E. Williams, Shreveport, La.; born in Hillsboro, Ohio, June 23, 1873; Chicago Homeopathic Medical College, 1901; Jefferson Medical College of Philadelphia, 1905; member of the American Medical Association; served as president of the Louisiana Homeopathic Board of Medical Examiners; fellow of the American College of Physicians; member of the advisory board of the Shreveport Charity Hospital and of the board of directors of the Pines Sanatorium; a founder of the Tri-State Hospital, where he died Oct. 4, 1947, aged 74, of cardiac decompensation and carcinoma of the prostate.

Wesley H. Wallace, Brooklyn; born in Alexandria Bay, N. Y., Nov. 9, 1869; Medical College of Virginia, Richmond, 1899; member of the American Medical Association; fellow of the American College of Physicians; formerly on the faculty of the Long Island College Hospital; during World War I a captain in the Third Field Hospital Unit of the New York National Guard and head of the local draft board; served as vice president of the Radiological Society of North America; on the staff of Methodist Episcopal Hospital, where he died Oct. 14, 1947, aged 77, of arteriosclerosis.

Carlos Green Webster, New York; born in Milan, Ohio in 1872; Cleveland University of Medicine and Surgery, 1896; New York Homeopathic Medical College and Hospital, New York, 1904; member of the American Medical Association; served during World War I; for ten years in the Ohio National Guard and for many years with the 258th Field Artillery Regiment of the National Guard in the Bronx, retiring in 1936 with the rank of lieutenant colonel; formerly on the staff of Flower and Fifth Avenue Hospitals; died Oct. 30, 1947, aged 75, of cerebral hemorrhage.

Adam Hancock Adamson, Arcadia, Kan.; University Medical College of Kansas City, Mo., 1913; member of the American Medical Association; died in Mount Carmel Hospital, Pittsburg, Oct. 21, 1947, aged 65, of coronary thrombosis.

Elmer Cleo Ambrose * Trenton, Mo.; National University of Arts and Sciences Medical Department, St. Louis, 1918; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; served during World War I; affiliated with Wright and Cullers hospitals; died in Washburne Point-Lake of the Ozarks, Oct. 15, 1947, aged 55, of coronary occlusion.

Elmer Lawrence Apple, Goldengate, Ill.; Hospital College of Medicine, Louisville, Ky., 1898; died October 23, aged 72, of angina pectoris.

Garnell Bailey, Evanston, Ill.; Meharry Medical College, Nashville, Tenn., 1931; died in the Evanston Community Hospital recently, aged 44, of hypertension.

William Harry Baker, West Buxton, Maine; Medical School of Medicine, Portland, 1901; member of the American Medical Association; died in Maine General Hospital, Portland, recently, aged 69, of hypertensive and arteriosclerotic heart disease and cellulitis.

Gill Wyeth Blackshear * Opelika, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1923; died Oct. 26, 1947, aged 49, of a fractured skull inflicted when thrown from a horse.

Milton Ralph Bookman, Los Angeles; Columbia University College of Physicians and Surgeons, New York, 1906; fellow of the American College of Surgeons; formerly affiliated with the Home for Hebrew Infants and the Lebanon Hospital in New York; died Oct. 4, 1947, aged 61, of coronary disease.

Warren Augustus Brewster, Callahan, Fla.; Medical College of Georgia, Augusta, 1900; member of the American Medical Association; died in Fernandina Oct. 13, 1947, aged 73, of angina pectoris and uremia.

James Henry Brooks, Decatur, Ga.; Atlanta College of Physicians and Surgeons, 1899; died recently, aged 79, of cerebral hemorrhage and arteriosclerosis.

Herbert Warren Canfield, Baxter, Iowa; Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1903; died in Newton Oct. 29, 1947, aged 70, of coronary thrombosis.

Bert B. Clark, New York; New York Homeopathic Medical College and Hospital, New York, 1899; died Oct. 5, 1947, aged 75.

Donald Lee Colglazier @ Indianapolis; Indiana University School of Medicine, Indianapolis, 1930; served during World War II; on the staff of the Methodist Hospital; died Oct. 16, 1947, aged 47, of carcinoma.

Wilfred Leslie Cooper, Los Angeles; Detroit College of Medicine, 1902; affiliated with the French Hospital; died Oct. 19, 1947, aged 71, of cerebral hemorrhage followed by coronary thrombosis.

Howard Clifton Crane, Kilbourne, Ohio; Starling Medical College, Columbus, 1894; died in the University Hospital, Columbus, recently, aged 83.

John Allen Crawshaw, Hanford, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; member of the American Medical Association; for many years health officer; died Oct. 18, 1947, aged 68, of internal hemorrhage.

Andre Alexander Cueto, Fort Lauderdale, Fla.; University of Cincinnati College of Medicine, 1934; member of the American Medical Association; died recently, aged 42, of coronary thrombosis.

William Loren Curtiss, Benton Harbor, Mich.; Eclectic Medical Institute, Cincinnati, 1895; Rush Medical College, Chicago, 1899; died Oct. 13, 1947, aged 79, of myocardial degeneration.

Henry Cecil Drew, Washington, D. C.; Georgetown University School of Medicine, Washington, 1909; served during World War I; for many years associated with the Veterans Administration; died Oct. 31, 1947, aged 61, of chronic endocarditis and hypertension.

Oscar F. Eckel, Asheville, N. C.; Medical College of the State of South Carolina, Charleston, 1906; past president of the Buncombe County Medical Society; member of the American Medical Association; for many years on the staff of the Mission Hospital; died Oct. 24, 1947, aged 68, of coronary thrombosis.

Harold Alexander Elder, Blowing Rock, N. C.; University of Pittsburgh School of Medicine, 1921; member of the American Medical Association and the Medical Society of the State of Pennsylvania; died recently, aged 53.

Henry Randall Elliott, Washington, D. C.; University of Virginia Department of Medicine, Charlottesville, 1895; associate professor in physiology at George Washington University; served on the staffs of the Emergency, Garfield and Doctors hospitals; died in University Heights, Ohio, Nov. 3, 1947, aged 73, of cerebral hemorrhage.

George I. Forbes, Burlington, Vt.; New York Homeopathic Medical College and Hospital, New York, 1893; member of the American Medical Association; served as member and treasurer of the state board of medical registration; affiliated with the Mary Fletcher and the Bishop De Goesbriand hospitals in Burlington and the Fanny Allen Hospital in Winooski; died Oct. 15, 1947, aged 82, of arteriosclerosis.

Augustus Harris Frye @ Griffin, Ga.; Atlanta Medical College, 1914; also a graduate in pharmacy; served overseas during World War I; died in Belfast, Maine, recently, aged 54, of heart disease.

James Frank Garrett, Greenville, S. C.; Medical College of the State of South Carolina, Charleston, 1922; member of the American Medical Association; died Oct. 2, 1947, aged 51, of heart disease.

Percy Emerton Gilbert @ Madison, Maine; Medical School of Maine, Portland, 1906; served on the staffs of the Presque Isle (Maine) General Hospital and the Franklin County Memorial Hospital in Farmington; died Nov. 1, 1947, aged 71, of cardiovascular disease and interstitial nephritis.

Albert Jefferson Green, Fairburn, Ga.; Emory University School of Medicine, Atlanta, 1916; member of the American Medical Association; died in Atlanta Oct. 23, 1947, aged 65, of pulmonary embolus.

Joseph Grice @ Portsmouth, Va.; University of Virginia Department of Medicine, Charlottesville, 1893; served as medical director of the city schools; died in the King's Daughters' Hospital Oct. 21, 1947, aged 78.

Frank Wood Hanford @ Los Angeles; Bennett Medical College, Chicago, 1905; served during the Spanish-American War and World War I; formerly on the staff of St. Anthony's Hospital in Rockford, Ill.; died in Birmingham Veterans Administration Hospital in Van Nuys, Calif., Oct. 29, 1947, aged 78, of coronary disease with infarction.

Howard Chapin Hanscom, West Boothbay Harbor, Maine; Columbia University College of Physicians and Surgeons, New York, 1900; at one time affiliated with the Western Maine Sanatorium in Greenwood Mountain; served as director of the bureau of institutional service, state department of health and welfare, in Augusta; died recently, aged 72, of heart disease.

Howard Elmer Johnson, Bird Island, Minn.; University of Minnesota Medical School, Minneapolis, 1942; member of the American Medical Association; interned at the Charles T. Miller Hospital in St. Paul; affiliated with Rice Memorial Hospital in Wilmar; died Oct. 26, 1947, aged 36, of coronary thrombosis.

John F. Kerr, Shelby, Ohio; the Hahnemann Medical College and Hospital, Chicago, 1881; died recently, aged 91, of senility.

William James Luxford, Decatur, Neb.; John A. Creighton Medical College, Omaha, 1909; died recently, aged 74.

Oliver McEuen, Hemingford, Neb.; St. Louis College of Physicians and Surgeons, 1889; died recently, aged 81.

Alton Terrill Peay, Signal Mountain, Tenn.; University of Nashville (Tenn.) Medical Department, 1889; Vanderbilt University School of Medicine, Nashville, 1889; died recently, aged 82, of senility.

Word Redwine, Madras, Ga.; Atlanta Medical College, 1895; died recently, aged 75, of cardiorenal disease.

Robert Gordon Rhoda, Allentown, Pa.; Jefferson Medical College of Philadelphia, 1947; served during World War II; intern at the Allentown General Hospital, where he died Oct. 23, 1947, aged 25, of poliomyelitis.

John Wagmon Rudder, Toxey, Ala.; University of Nashville (Tenn.) Medical Department, 1907; member of the American Medical Association; died Oct. 27, 1947, aged 65, of cerebral hemorrhage.

Thomas Littleton Savin, Little Rock, Ark.; University of Maryland School of Medicine, Baltimore, 1897; member of the American Medical Association; died in the Baptist State Hospital Oct. 3, 1947, aged 72, of lymphatic leukemia.

Frederick J. Schmoldt @ Cleveland; Western Reserve University Medical Department, Cleveland, 1898; member of the Cleveland Academy of Medicine and the Cleveland Medical Library; on the staff of St. Alexis Hospital, where he died Oct. 16, 1947, aged 74, of hypertension.

Felix Herbert Schubert, Los Angeles; College of Medical Evangelists, Los Angeles, 1934; member of the American Medical Association; affiliated with the Physicians and Surgeons Hospital and the Glendale Sanitarium and Hospital, where he died recently, aged 43, of uremia, hypertension and nephrosclerosis.

Hugo Paul Siekert @ Milwaukee; Marquette University School of Medicine, Milwaukee, 1916; affiliated with St. Anthony's Hospital; died recently, aged 55, of coronary thrombosis.

Matthew A. Stewart, Heavener, Okla. (licensed in Oklahoma under the Act of 1908); died recently, aged 71.

Melville Abbott West, Cheney, Wash.; University of Oregon Medical School, Portland, 1914; served as city health officer; affiliated with St. Luke's Hospital in Spokane; died Oct. 19, 1947, aged 63, of arteriosclerosis and heart disease.

John Rufus Wilson, Terre Haute, Ind.; Northwestern University Medical School, Chicago, 1892; College of Physicians and Surgeons, Keokuk, Iowa, 1898; member of the American Medical Association; died in St. Anthony's Hospital Oct. 27, 1947, aged 78, of bulbar paralysis and cerebral sclerosis.

W. Lewis Wilson @ Niagara Falls, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1904; died recently, aged 70, of pulmonary edema.

Joseph Walker Wynne @ Newbern, Tenn.; Vanderbilt University School of Medicine, Nashville, 1894; died recently, aged 78, of tuberculosis.

Research on the Common Cold

A research project on the common cold, set up by the Medical Research Council and the Ministry of Health, has been conducted for eighteen months by experiments with human volunteers on a scale never equaled in any other country. So far 500 volunteers, men and women, have taken part; even honeymoon couples have been among those who have submitted to the tests. The research has a twofold aim: to identify beyond doubt the nature of the virus causing the common cold, and to establish how colds are transmitted from person to person. Already two important discoveries have been made. It has been established that the size of the type of virus which causes colds is roughly 0.0001 mm., which is about the size of the influenza virus. It is too small to be seen through the most powerful microscope in this country, and its size has to be estimated through special filters. New facts have been elucidated about the conditions under which the virus preserves its activity. For example, it can withstand freezing temperatures as low as minus 70 C.

EFFORTS TO GROW THE VIRUS HAVE FAILED

Research has been concentrated on trying to grow the virus in the laboratory on eggs, but has proved unsuccessful. For long term research of this type a regular flow of volunteers is necessary, so that interruption of the work is avoided. Volunteers are accommodated in groups of 24. They live in pairs in complete isolation from other human contacts for ten days. Before the test each must be free from any symptoms of a cold. They then have instilled into the nose drops of carefully prepared fluid, which in some cases is believed to contain the cold virus. Then a close check is kept to see whether or not colds develop. On an average 1 of every 3 volunteers contracts a cold. None has been of a serious kind.

There is little difficulty in getting students as volunteers during university vacations, but for other periods volunteers are not so easy to get. Next year several hundreds are wanted. Normally persons of either sex between the ages of 18 and 40 are required. These volunteers get ten days' free holiday with 75 cents pocket money. They can go for walks or play games. Many have liked the experience so much that they have come back for a second and even for a third visit. This is allowed after a six months' interval. Application forms with full details of the test and dates are supplied on request.

Sherrington's Ninetieth Birthday

Sir Charles Sherrington, the eminent neurophysiologist, attained his ninetieth birthday on November 27. His crowning work, "The Integrative Action of the Nervous System," marks an advance in the physiology of the nervous system which has been compared to that due to Harvey's "De Motu Cordis" and Newton's "Principia." At the Physiological Congress held in England earlier in the year a new printing of Sherrington's great work was presented to all the members. In celebration of his ninetieth birthday the *British Medical Journal* has published a series of articles, which begin with "Sherrington's Impact on Neurophysiology" by Professor John F. Fulton of Yale. He points out that Sherrington's paper, "On the Anatomical Constitution of Skeletal Muscles," published in 1894, laid the foundation of knowledge of what he later termed "the proprioceptive system." Previously textbooks on anatomy had assumed that

all nerves going to muscle were motor. The early phases of Sherrington's work culminated in his Stillman Lectures at Yale University in 1904 under the title, "The Integrative Action of the Nervous System." There he introduced a host of new terms and phrases which have become current in modern neurophysiology—synapse, proprioceptive and nociceptive. His concept of integrative action revived the Hughlings Jackson concept of release of function to account for decerebrate rigidity and the rigidity of hemiplegia.

The philosophic implications of Sherrington's studies on the nervous system have often been discussed, but he remained almost stubbornly silent on the subject until his Rede lectures delivered at Cambridge in 1933. He returned to the subject in his foreword to the 1947 edition of "The Integrative Action of the Nervous System." He wrote: "In all those types of organism in which the physical and the mental coexist, each of the two achieves its aim only by reason of a *contact utile* between them. And this liaison can rank as the final and supreme integration completing its individual. But the problem of how that liaison is effected remains unsolved; it remains where Aristotle left it more than two thousand years ago."

Treatment of Syphilis in France

The treatment of syphilis in France has undergone modifications, which have not, however, changed the general method of treating syphilis as established by solid experience. Professors H. Gougerot and R. Degos, at the conference of the International Union Against Venereal Disease, stated that three principal methods are equally favored by French doctors: (1) arsenic-bismuth treatment, which has become classic in France; (2) bismuth preparations alone, and (3) penicillin and combined penicillin-bismuth therapy. Numerous French syphilologists prefer to exclude arsenic from the treatment of syphilis because of, first, the apparently high number of serious accidents, even deaths, provoked by the arsenicals, arsenobenzols and arsenoxides, and second, the ease of application, the innocuousness and the satisfactory results obtained from the exclusive use of a bismuth compound. R. Degos, E. Lortat-Jacob and P. Maury have just reported their first comparative results on a series of seropositive patients with primary and secondary syphilis treated with arsenicals, penicillin and bismuth compounds, alone or combined and in various doses. The best effects on the serologic titer were obtained from an initial treatment of twenty injections of a bismuth preparation in oil, three injections per week throughout the duration of the treatment: 100 per cent of patients were serologically negative after the first series of injections.

In France penicillin has been used chiefly as the first treatment of early syphilis, in most cases at a total dosage of 2,400,000 units, with 40,000 units given every three hours for seven and one-half days. Many French syphilologists increase the total dose to 3,600,000 and 4,000,000 units. The experiments of Professor Gougerot and J. Schneider have shown that the clinical results obtained on primary or secondary manifestations are the same with pure penicillin G ("specilline") as with penicillin containing no penicillin G. A negative serology is obtained quicker with penicillin G. This antibiotic constitutes a rapid initial sterilizing treatment, but its immediate effect should be followed by an intensive and prolonged consolidating treatment of many years. At present French syphilologists prefer mixed penicillin-bismuth treatments; the majority has adopted the method of Professor Gougerot (based on the clinical and experimental work of Levaditi and Vaisman): 2,400,000 units of penicillin administered in divided doses over seven and one-half days

and injections of a bismuth preparation in normal doses the first, third and seventh day. After the end of "the penicillin cure," the bismuth compound is continued at the rate of two injections per week for a total of twelve, then such initial combined treatment is followed by bismuth therapy alone.

New Test for Hypocalcemia

In a study of hypocalcemia (spasmophilia) H. P. Klotz and R. Klotz-Valensi, on Professor Bezancon's service, tried to test the strength of the parathyroids, the calcium regulators. They induced hypocalcemia in order to observe the time required to recover from it. They used estradiol benzoate to produce hypocalcemia on account of the frequency of premenstrual tetany, which has been stressed by Pende, Maranon, Richet, Coste and others. The test consists in an intramuscular or deep subcutaneous injection of 20 mg. estradiol benzoate immediately after determining the blood calcium level prior to beginning the test. An hour or two later the blood calcium is again ascertained. (The results of the test after the second hour are the more reliable.) The test made on more than 80 patients with spasmophilia showed on the average a blood calcium level 10 to 15 per cent lower in a few hours; in 1 case it was reduced 30 per cent. The test is considered positive when a 5 per cent lowering has been obtained. On nonspasmophilic subjects the blood calcium remained unchanged. On parathyroprivals induced hypocalcemia always has been exceedingly distinct and prolonged, up to twenty-four hours at times. The authors have made the test in some cases of chronic tetany after ablation of a goiter. This test has great clinical value for the diagnosis of certain forms of spasmophilia. It enables one to diagnose as hypocalcemia the disease of patients presenting themselves as cardinals or neuropaths, who are improved by recalcifying therapy (calciferol in sufficient doses). When the test is negative, it permits absolving spasmophilia in purely psychogenic or in certain epileptic crises, which were believed to be essential. The test is positive in man as well as in woman and is independent of the menstrual cycle; in children it is valid with half doses. As regards prognosis, it helps one to appreciate the seriousness of the calcium regulative difficulty by means of the duration of the calcium lowering. In chronic tetany related to surgical or idiopathic hypoparathyroidism the lowered level persists twenty-four hours during the first months and becomes transitory in the course of improvement. Research is in progress on the physiopathologic interpretation of induced hypocalcemia.

Congress on Hygiene of Schools and Universities

Under the presidency of Professor Lesne, Great Britain, Netherlands, Belgium, Denmark, Sweden, Switzerland, Italy, Roumania, Iran, Egypt, the United States, Argentina, Brazil, Colombia and Canada sent official representatives to the Congress on Hygiene of Schools and Universities. On the agenda were: pupils' growth disorders during and after the war; rational organization of school work in secondary, high and technical schools; alimentation at school; corrective gymnastics, and the detection of tuberculosis by radiologic examinations. On all these subjects French and foreign delegates made reports and communications. The congress passed the following resolutions:

1. *General Hygiene.*—To protect sleep and the need for movement, shorten the classes, increase recreation and divide holidays more appropriately; to prohibit the meeting of adults in the schools, to lighten the programs of studies and to better living conditions of students.
2. *Special Hygiene.*—To increase the teaching for deficient pupils by increasing the special classes.
3. *Dental Hygiene.*—To detect dental decay in school children.
4. *Alimentary Hygiene.*—To improve canteens and in general provide a supplementary diet.

Delegates from the nineteen countries that were represented voted to create the International Association of School Hygiene.

Professor Lesne was elected president and Dr. Delthil, general secretary. The latter proposed that the International Association have its headquarters in Paris. International Congresses will be periodically organized.

BUENOS AIRES

(From Our Regular Correspondent)

Dec. 10, 1947.

Experimental Bronchogenic Emphysema

In continuance of earlier experimental and clinical work, Professors M. R. Castex and E. S. Mazzei and Drs. J. M. Remolar and E. S. Pedace have been able to produce bronchogenic emphysema in dogs, using the method of John R. Paine (*J. Thoracic Surg.* 10:150, 2, [Dec.] 1940) with slight modification. Following experiments on 16 dogs, they conclude that pulmonary emphysema can be obtained in various degrees and that it reproduces the different stages which are observed in the human clinic, viz., alveolar dilatation, anatomic emphysema and also ampullary emphysema. These different stages and grades depend more on the intensity of the respiratory obstructive process than on the time of its evolution. If this experimental emphysema is accentuated and generalized, it is characterized by the symptoms of dyspnea corresponding to the degree of the obstruction. When the respiratory obstruction is more extensive, the emphysematous lesions are also greater and more generalized and appear earlier. The heart of the dog with experimental emphysema exhibits almost constantly changes in anatomic structure which reproduce in different degrees those which in the human being are found in the chronic pulmonary heart (enlargement and right ventricular dilation).

In these experiments, the ampullary emphysema and the chronic pulmonary heart were produced experimentally for the first time.

Argentine Congress of Tuberculosis

The Argentine Congress of Tuberculosis assembled with Professor Raúl Vaccarezza, of the Medical Faculty of Buenos Aires, as president. In his inauguration speech he stressed that tuberculosis is rapidly and distinctly diminishing. The decrease is so considerable that Dublin has prognosticated that in 1960 there will not be any more tuberculosis in the United States. According to Dr. Vaccarezza, the mortality per hundred thousand in the United States was 200 in 1900 and 40 in 1945, and in Argentina, 182 in 1921 and 93 in 1941. He said that in the whole Argentine Republic there are some 400,000 persons with active tuberculous lesions; 160,000 of them are aware that they are ill, but the others do not know it. Furthermore, it has been estimated that in 1936 the economic loss caused by the known patients was 280,000,000 pesos; this does not count the unknown tuberculous persons nor include the expenses for social protection of the patient's family or those of the institutions for prophylaxis and prevention.

The official subjects of the meeting were rehabilitation of the tuberculous patient, hematogenous tuberculosis and thoracoplasty for the treatment of tuberculosis of lungs. In continuation of this congress the Argentine Society for Tuberculosis held a two day meeting on treatment of cavities of the inferior lobes and lung resections for tuberculosis.

Congress of Obstetrics and Gynecology

The Argentine and Uruguayan specialists assembled for three days in Buenos Aires. The first two reports were on "The Actual Value of Surgery in Uterine Retrodisplacements" and "The Actual Value of Biologic Tests for the Diagnosis of Pregnancy." Other main subjects were "The Value of Methods of Induction of Parturition" and "The Value of Penicillin Therapy in Gynecology."

VENTRICULAR FIBRILLATION ABOLISHED BY ELECTRIC SHOCK

To the Editor:—The case report, "Ventricular Fibrillation of Long Duration Abolished by Electric Shock," by Beck, Pritchard and Feil (*THE JOURNAL*, Dec. 13, 1947, p. 985) describes a rare and remarkable accomplishment in operating room therapeutics. It is also, however, a clear example of the misuse of a cardiac glycoside in the operating room.

There has long been great need for better understanding of the value and effects of digitalis preparations in the patient undergoing anesthesia and operation. Their abuse in the treatment of peripheral circulatory failure is notoriously common as part of the "medical last rites." So is their application for resuscitation during any type of anesthetic accident. But the case reported is the first I have encountered in which a digitalis preparation has been used to decrease a tachycardia under anesthesia with the result that a near fatal ventricular fibrillation was produced by the cardiac glycoside, lanatoside C. The errors, as I see them, are the following:

1. The use of a cardiac glycoside was not indicated for the slowing of a tachycardia of 160 during induction with nitrous oxide and ether of anesthesia in a patient 14 years of age with a heart slightly displaced in a severe congenital funnel chest, dyspnea on exertion, normal venous pressure and circulation time. The tachycardia might have been due to anoxia or respiratory obstruction during the administration of the anesthetic or to excessive sympathetic nervous activity excited by induction of anesthesia without adequate sedative premedication. Ether per se may stimulate such hyperactivity; or atropine premedication may permit the escape of a sinus tachycardia. If the tachycardia was thought to be due to acute heart failure during induction, the operation, being elective, should have been postponed. If the tachycardia was due to a paroxysm of auricular fibrillation, again the operation should have been postponed; if it could not be postponed then the lanatoside C should have been administered in fractions of the complete dose with the ventricular rate as a guide to additional doses. If the tachycardia was regular and of sinus origin, as it probably was, then a cardiac glycoside was not indicated. "In the light of present data it may be said that with few exceptions slowing of the normally beating heart from direct action at the pacemaker of digitalis in therapeutic amounts is so slight as to be negligible, if indeed it occurs" (Luten, D.: *The Clinical Use of Digitalis*, Baltimore, Charles C Thomas, 1936, p. 48). "Since the attainment of clinical results from the direct sinus action of digitalis in therapeutic amounts is problematical, aside from the propriety of trying to induce them, it is obvious that no indication exists for obtaining such effects" (Luten, p. 49). "Large toxic doses can notably depress the sinus node leading to conspicuous cardiac slowing" (Movitt, E. R.: *Digitalis and Other Cardiotonic Drugs*, New York, Oxford University Press, 1946, p. 29). "The sinus slowing reported in many cases both in children and in adults, as an expected result of therapeutic action, is in fact a manifestation of toxic effect . . . with few exceptions slowing of the normally beating heart from therapeutic amounts of the drug is inconspicuous, and . . . greater degrees of slowing occur only with excessive dosage" (Luten, p. 63). It appears that these statements apply accurately to this case. The prompt effect of the lanatoside C in slowing the heart rate to 80 confirms the belief that a toxic dose was administered at the beginning of the operation.

2. If it be granted that a cardiac glycoside was required, the adult dose of 1.6 mg. of lanatoside C was obviously

excessive for a boy aged 14, even though he was large for his years.

3. The appearance of ventricular fibrillation after two hours, during the closure of the wound, was not recognized as a toxic effect of the overdose with lanatoside C. Yet it should have been no surprise in view of the fact "that ventricular fibrillation in human beings occurs from poisonous doses of digitalis . . . that it is a common result in cases of fatal poisoning from the drug, and that it is the ultimate cause of death in many of the instances of sudden death occurring unexpectedly in patients after large doses of digitalis" (Luten, p. 64). The arrival of ventricular fibrillation approximately two hours after injection of lanatoside C coincides with observations that the maximum effects of intravenous lanatoside C in normal subjects appear in one to six hours (Movitt, p. 94) and in patients with congestive failure in two to three hours (Movitt, p. 94).

4. The administration of epinephrine intravenously during cardiac resuscitation is of doubtful value. But the dose of 1 mg. is certainly excessive for this route and is dangerous, especially for the digitalized patient, since "it has been shown that only half of the usual lethal dose of adrenalin is necessary to kill animals receiving nonlethal doses of digitalis" (Movitt, p. 56). It is apropos to mention here that degenerative changes in the myocardium produced by toxic doses of digitalis are potentiated by adrenalin (Movitt, p. 56).

5. The administration of another dose of lanatoside C at the time of cardiac resuscitation demonstrated ignorance of the foregoing facts and exemplified the classical misuse of digitalis bodies for "circulatory stimulation" during circulatory mishaps associated with anesthesia and surgery.

The educational merit of the published case is greater than intended by the authors. Their clear reporting truly illustrated the latest advances in cardiac resuscitation. It also, however, demonstrated the importance of (a) accurate diagnosis of the cause of a physiologic disturbance during anesthesia, (b) proper therapy of a disturbed physiologic state during anesthesia and operation and (c) adequate knowledge of digitalis and digitalis-like bodies, particularly as they are related to other drugs employed during anesthesia.

BARNETT A. GREENE, M.D., Brooklyn.

THE NURSE ANESTHETIST

To the Editor:—At the recent meeting of the Southern Surgical Association, which was held in Hollywood, Fla., Dec. 9, 10 and 11, 1947, the following resolution was passed unanimously by the Association:

"Although the Southern Surgical Association has been and always will be extremely interested in the advancement of all medical sciences, and particularly in anesthesia because of complete dependence on safe anesthesia for the safe performance of a surgical procedure, it, the Southern Surgical Association, heartily disapproves of the publicity given by certain newspapers and popular lay magazines to the statements sponsored by a group of anesthesiologists who are seeking to discredit the well trained nurse anesthetist and to compel surgeons to operate only if anesthetics are administered by physician-anesthetists.

"This attempt to persuade the public that there is grave danger in a surgical operation if the anesthetist is not a certified medical specialist is already decreasing the number of efficient well-trained nurse anesthetists and forcing surgeons to perform recently developed complicated operations with anesthetics administered by young hospital interns or general practitioners, neither of whom have special training or experience in the administration of an anesthetic."

ALFRED BLALOCK, M.D., Baltimore.
Secretary, Southern Surgical Association.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in THE JOURNAL, Jan. 17, page 204.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Examination.* Montgomery, June 22-24, 1948. Sec., Dr. G. G. Gill, 519 Dexter Ave., Montgomery 4.

ALASKA: * *Examination.* Juneau, March 2. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

ARKANSAS: * *Examination.* Little Rock, June 3-4. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic:* Little Rock, June 3. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Oral.* San Francisco, June 5-6; Los Angeles, Feb. 28-29. *Written Examination.* Los Angeles, March 1-4. *Oral and Clinical Examination for Foreign Graduates.* Los Angeles, Feb. 29; San Francisco, June 6. Sec., Dr. Frederick N. Scatena, 1020 N Street, Sacramento 14.

CONNECTICUT: * *Examination.* March 9-10. Sec., Dr. Creighton Barker, 258 Church St., New Haven. *Homopathic Examination.* Derby, March 9-10. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

DISTRICT OF COLUMBIA: * *Reciprocity.* Washington, D. C., March 8. Sec., Commission on Licensure, Dr. G. C. Ruhland, 4130 E Municipal Bldg., Washington.

FLORIDA: * *Examination.* Jacksonville, June 29-30. *Reciprocity.* Jacksonville, June 28. Sec., Dr. Harold D. Van Schaick, 6675 Windsor Lane, La Gorce Island, Miami Beach 41.

INDIANA: *Examination.* Indianapolis, June 1948. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, K of P Bldg., Indianapolis.

IOWA: * *Examination.* Iowa City, March 15-17. Comm., Dr. Walter L. Bierring, Dept. of Health, Des Moines.

KANSAS: Kansas City, June 9-10. Sec., Board of Medical Registration & Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: *Examination.* Louisville, June 16-18. Sec., Dr. P. E. Blackerby, 620 S. 3d St., Louisville.

MAINE: Portland, March 9-10. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

MARYLAND: *Medical Examination.* Baltimore, June 15-18. Sec., Treas., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homopathic Examination.* Baltimore, June 15-16. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: *Examination.* Boston, March 9-12. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413 E State House, Boston.

MISSISSIPPI: Jackson, June 1948. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: Helena, April 5-7. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

NEVADA: Carson City, May 3. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: *Examination.* Concord, March 11-12. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

NEW JERSEY: *Examination.* Trenton, June 15-17. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW YORK: *Examination.* Albany, Buffalo, New York, Syracuse, Feb. 16-19. Sec., Dr. J. L. Lochner, Jr., Education Bldg., Albany.

OHIO: *Endorsement.* Columbus, April 6. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

SOUTH CAROLINA: *Written Examination.* Columbia, June 21-23. *Endorsement.* Feb. 2. Sec., Dr. N. B. Heyward, 1329 Blinding St., Columbia.

TEXAS: Austin, Feb. 19-21. Asst. Sec., Mrs. Laura McElroy, 918-20 Texas Bank Bldg., Dallas 2.

UTAH: *Examination.* Salt Lake City, June, 1948. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

VIRGINIA: *Examination.* Richmond, June 18-19. *Endorsement.* Richmond, June 17. Sec., Dr. K. D. Graves, 306 Medical Arts Bldg., Roanoke.

VERMONT: *Examination.* Burlington, Feb. 5-6. Sec., Dr. F. J. Lawliss, Richford.

WYOMING: *Examination.* Cheyenne, Feb. 2. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ALASKA: Juneau, Feb. 23-29. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

DISTRICT OF COLUMBIA: *Examination.* Washington, April 19-20. Sec., Dr. G. C. Ruhland, 4130 Municipal Bldg., Washington.

FLORIDA: *Examination.* June 5. Final date for filing application is May 23. Sec., Mr. M. W. Emmel, Univ. of Florida, Gainesville.

IOWA: Des Moines, April 13, July 13, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

OKLAHOMA: Spring 1948. Sec., Dr. Frank Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: *Examination.* Portland, March 6. Sec., Basic Science Examining Committee, Mr. C. D. Byrne, Univ. of Oregon, Eugene.

WISCONSIN: *Examination.* Madison, April 3. Sec., Dr. W. H. Barber, Scott & Watson Sts., Ripon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Vaccination by Nurse as Unlicensed Practice of Medicine.—Defendant was charged with the unlicensed practice of medicine and with an assault in the third degree. Her motion for a dismissal of the charges was heard in the magistrate's court of the city of New York, felony court.

The defendant, allegedly a practical nurse, set up quarters in a bar and grill in the city of New York and, while professing to inject persons with vaccine serum, injected some 500 persons from a syringe containing water. A police officer happening to pass the establishment and observing the proceedings approached the defendant and took the needle from her hand. He gathered up several other needles, some from a pot on the stove in the rear of the restaurant where they were being apparently sterilized in water. The defendant told the police officer that she had worked as a practical nurse and that she was vaccinating the persons in line. She later admitted to the officer that she was using merely water for inoculating purposes and not any serum whatever. She made the further statement that she had had no purpose other than wanting to impress her boy friend with her efficiency as a nurse; they had had some disagreement and she felt, to use her words, "that she would make a hit with him." She further made the startling statement that during two days she had vaccinated five hundred persons by inoculation.

The defense contended that there was no violation of the education law in that the acts committed by the defendant did not amount to the practice of medicine. Section 1250, subdivision 7, of the education law reads: "The practice of medicine is defined as follows: A person practices medicine within the meaning of this article, except as hereinafter stated, who holds himself out as being able to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition, and who shall either offer or undertake, by any means or method, to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition." It is argued that the vaccination was not a diagnosis, an operation, a treatment or a prescription and further that all of the aforesaid terms presupposed the existence of human disease or disorder. Treatment, said the court, is a very general term. Vaccination is a treatment given to a human being, even though no disease is present, to prevent disease on the assumption that human beings are susceptible to disease particularly of the contagious kind such as smallpox. It is treatment as well as preventive medicine. In our modern age the great progress of science is evidenced among other things by preventive medicine, which is adopted even before disease makes its appearance and precisely to bar it from the human organism. That, too, must be construed to be the practice of medicine. The purpose of the statutes in the education law concerning the practice of medicine is to protect not merely the profession but also the general public.

The defendant herein held herself out, the court continued, as qualified to give those whom she injected such treatment as would prevent smallpox. She was not a duly qualified or licensed physician. It may be argued here, said the court, that the defendant did not practice medicine for the very reason that she was perpetrating a hoax. The gravamen is in having held herself out as qualified and as intending to offer proper treatment. She lulled persons into a sense of security when they needed and sought such treatment from her, relying on her false pretenses. That is the theory on which the quacks and other unlicensed persons have been convicted. That in this instance the fraud was greater cannot destroy the principle of "pretending to protect the public from falling into the hands of the unauthorized, who cannot or will not offer proper treatment." It was not essential for the defendant to claim to be a physician to bring her acts within the statute. She held herself out as qualified when she offered to perform the acts recited in the complaint.

It is further contended that the defendant cannot be guilty of assault of the third degree as the defendant did not intend any bodily harm, since the injection of water was harmless and since her acts were committed with the consent of the persons allegedly assaulted. At the time the defendant vaccinated several persons, she knew that there was fear of an epidemic and that the health commissioner of the city had been so concerned with its potentialities that he had himself, as well as the mayor of the city and many other agencies, urged the people to submit to vaccination. Five hundred, evidently very simple persons, had applied to the defendant herself when she set up quarters in a bar and grill with syringe and other apparatus to perform what might have been a tragic hoax on innocent persons and only to impress her boy friend. She knew they were not being immunized and she knew that it was only water and not vaccine serum that had been injected. The puncturing of the body of another person with a needle in the circumstances was certainly an assault. It is true that as a rule consent, if intelligently given, is a good defense in assault. There are, however, limitations to the rule. The consent must be voluntary and intelligent. It must be free from force or fraud. Consent is the affirmative act of an unconstrained and undeceived will. The general principle seems to be also that the act performed should not exceed the extent of the terms of consent. Certainly in this instance the persons who submitted to vaccination could not consent to the perpetration of such acts as were committed by the defendant in this case. It not only subjected the person injected to violence, but it was also a menace to the community. There was no consent willfully given. The persons submitted to the defendant under the pretext of her authority and under the profession of her mission. They thought that a duly authorized person was immunizing them against a dreaded disease. It was certainly an assault under the circumstances. Accordingly the defendant's motion for dismissal of the charges was denied and the defendant was held for trial in the court of special sessions. —*People, on Complaint of Burke, v. Steinberg*, 73 N. Y. S. (2d) 475 (N. Y., 1947).
